Abstract

Economic regulation injects the state into firms' pricing, entry, investment, and product decisions. The empirical study of economic regulation has evolved considerably since George Stigler's seminal work in 1962. An extensive literature analyzes the effects of regulation in both natural monopoly and structurally competitive industries. This work suggests that regulation can have significant effects on prices, rent creation and distribution, costs, and technological innovation. Current policy and research activity focuses on restructuring and market design in traditional natural monopoly sectors and on the shift toward market-based or incentive regulation. Myriad worldwide policy experiments provide a rich set of observations for empirical analysis. Early results suggest some unanticipated consequences, and highlight the importance of institutional detail in market design.

The economic regulation of firms and industries constitutes an extreme form of government intervention in markets. Government antitrust, competition, tax, and trade policies, as well as most environmental, health, safety, and information regulations, shape but do not replace the market, although the most severe of these policies may blur that distinction. Economic regulation stands in sharp contrast. In industries subject to economic regulation, government agencies or departments exercise considerable control over firms' entry, pricing, investment, and product choice decisions, and administrative decisions replace market outcomes. Intervention may go as far as replacing private ownership with government-owned and -operated enterprises.

The modern field of empirical regulatory economics developed during the 1960s and early 1970s, as economists began "to apply the familiar principles of microeconomics in comprehensive fashion to the subject" (Kahn, 1988: p. xv). George Stigler, whose contributions to the field were recognized in his 1982 Economics Nobel prize citation, sparked much of this growth. Through the 1980s, economists focused on quantifying the effect of regulation on firm behavior, industry outcomes, and consumer welfare. The diversity of regulatory forms and industry characteristics across the transportation, energy, utility, financial, and communication sectors provided a rich set of institutions for investigation. Significant policy reforms, even deregulation, in structurally competitive sectors during the 1970s and 1980s provided new sources of variation in the regulatory environment and invigorated empirical regulatory research. More recent attention has turned to the traditional 'public utility' sector, particularly the telecommunication and electric utility industries. Market-based institutions have begun to replace state-ownership and regulation, as technological change called into question the natural monopoly assumption in many of these industries and policy interest in privatization raised questions of how best to restructure and sell-off vertically integrated monopolies. Analyzing the operation of these, redesigned markets has become a main focus of empirical regulatory research.

This article focuses on empirical analysis of the effects and reform of economic regulation. Section Empirical Methodologies describes the dominant empirical methodologies. Section The Effects of Traditional Economic Regulation sketches the evidence on the effects of traditional economic regulation. Section The Effects of Restructuring Regulated Natural Monopolies discusses recent analyses of market design and regulatory scope. To keep the reference list manageable, readers are referred to surveys and collective volumes wherever possible. These guide readers interested in delving more deeply into particular issues to a wealth of primary studies.

Empirical Methodologies

Measuring the effect of economic regulation requires the establishment of a counterfactual benchmark: what would firm or industry performance look like in the absence of regulation? A variety of approaches to this have been used. The most compelling lesson of the existing literature is that the impact of economic regulation depends critically upon its particular institutional form and the characteristics of the industry under study. Measuring the impact of regulation requires as much attention to the details of how regulators operate in practice as to the prescribed legal form of the regulation. Paul Joskow's (1974) study of electric utility regulation in the US provides a persuasive exposition of this argument.

The most common methodology used to measure regulatory effects compares outcomes in regulated markets with those in unregulated markets. Time series variation may facilitate this comparison; the wave of US deregulation in the late 1970s and early 1980s generated numerous 'before-and-after' studies of regulation. Differences across political jurisdictions, e.g., across states within a country or across countries, may provide another source of variation in regulatory regimes. Empirical studies also may use differences in the intensity or form of regulation to infer its effects, particularly if regulation is likely to bind only under certain well-defined circumstances.

Two conditions limit the usefulness of this approach. First, unregulated comparisons may not exist. Industries that are regulated in one political jurisdiction tend to be regulated or government owned in other political jurisdictions. Regulation may be so long-lived that comparing current regulated performance with historical unregulated performance is meaningless.

Second, this method implicitly assumes that differences in regulatory regimes are exogenous to firm or market performance. This is often false. If, for example, jurisdictions impose electricity regulation in response to high or rapidly increasing local electricity rates, comparing price levels in regulated and unregulated locales might suggest no effect even if regulation does, in fact, constrain prices. Using panel data to estimate effects from 'differences in differences' econometric models may be useful in some cases, as may developing more complete models of the determinants of regulation.

A second methodology estimates a structural model of the market, forms assumptions about behavior in the absence of regulation, and compares simulated unregulated outcomes with those observed under regulation. This technique may be useful even in the absence of regulatory variation. It is most appropriate when regulatory constraints can be clearly specified. Suppose regulators constrain prices but do not influence investment or factor use decisions. Structural estimates of underlying demand and cost functions permit one to predict unregulated profit-maximizing prices and compare these with current regulated prices. If regulated firms do not minimize costs, however, or if regulatory intervention alters investment decisions in a systematic way, then the regulated cost function may be a poor estimate of the unregulated long-run cost function, and the implied price comparison will be misleading.

A third approach uses experimental data to measure regulatory effects. Field experiments, such as the time-of-use electricity pricing studies conducted in the US during the early 1970s, can reveal responses to alternative regulatory or market designs. In the best of circumstances, these can provide information on how market outcomes respond to exogenous variation in regulatory mechanisms, holding other economic conditions constant. Their cost limits their widespread use, however, and their temporary nature may preclude an assessment of long-run equilibrium responses to alternative policies. Laboratory experiments, which present volunteers (often students) with a set of objectives, operating guidelines, and payoffs, also have been used in a limited way to simulate responses to alternative regulatory designs.

The Effects of Traditional Economic Regulation

It is impossible to describe succinctly the full effects of economic regulation across industries, over time, and through space. Regulation may influence prices, costs, and the pace of technological change in an industry. This may lead to the creation or suppression of economic rents, and change the distribution of rents across various stakeholders or interests in the industry. These effects are likely to vary considerably across markets and regulatory forms, and preclude simple generalizations. This article highlights some illustrative results. Further detail is provided in the many reviews referenced at the end of this article and the primary sources they cite.

Empirical Analysis of Natural Monopoly Regulation

Industries such as electricity supply, telecommunications, natural gas transmission and distribution, water and sewer service, cable television service, and to some extent railroads have historically been considered 'natural monopolies.' This applies when total production costs are minimized by providing service to all customers in a given market through a single firm. As economists since Adam Smith have recognized, minimizing production cost may not minimize price, since monopolies use their market power to markup price above competitive levels and earn monopoly rents. This historically engendered one of two policy responses. Government ownership in natural monopoly sectors was typical outside the USA, and was used frequently in the USA for water and sewer service, but less so for electric utilities and cable television service. Government regulation of privately owned firms was the dominant US response in most other cases. In this scheme, regulators typically grant a legal, 'franchise' monopoly to a single provider in a geographic market, but retain control over price to mitigate the monopoly markups that an unconstrained legal monopolist would choose. Prices are determined generally by commissions that review costs, and often investment decisions, and set prices to cover allowable costs and a 'fair rate of return' on 'prudent' capital investments.

Early economic research on the regulated public utility sector was generally theoretical and focused on how to perfect regulatory pricing, treating as given the desirability and general effectiveness of government regulation. Optimal pricing questions also arose for state-owned utility enterprises, and French and British economists were in the vanguard of research in this area (Kahn, 1988; Laffont, 1994; *see* Poverty: Measurement and Analysis). Stigler and Friedland's (1962) study of the early electricity industry was one of the first empirical analyses of the actual effect of utility regulation, and concluded that regulation did little to reduce prices below unregulated monopoly levels. While the particulars of this research generated controversy at the time, and subsequent work suggests that electricity prices in the Friedland–Stigler sample were, in fact, lower for regulated firms (Peltzman, 1993), the notion that regulation might not improve upon market outcomes even in those sectors with the strongest public interest rationale stimulated considerable additional research.

The literature subsequent to Stigler and Friedland (1962) suggests generally that price regulation, particularly in the electricity and cable television industries, has constrained average prices below the level an unconstrained legal monopolist would choose. Analysis of average price levels masks the effect of regulation on price structures, however. Price structure analyses in electricity and telephone industries suggest redistributive rather than Ramsey-like efficient pricing objectives, often with considerable transfers from customers with relatively elastic demands to those with relatively inelastic demands. For example, regulatory cross-subsidies from long-distance telephone rates to basic residential telephone service and from urban to rural telephone customers were a major force driving new entry into the US long-distance sector, leading ultimately to the 1984 divestiture of AT&T and the regulatory reform of the telephone industry. The tenacity of these cross-subsidies more than 15 years later testifies to the strength of political interests supporting these policies. Some economists have estimated the social welfare cost of the residential service cross-subsidy to be as high as $7.0 billion per year (in Peltzman and Winston, 2000: p. 78).

The effect of natural monopoly regulation on static production costs is less well measured. One of the most developed theoretical and empirical literatures on incentives for excessive capital investment in rate-of-return regulated industries proved largely inconclusive (Averch and Johnson, 1962; Joskow and Rose, 1989). There is some evidence of higher wages in firms that expect regulators to flow increased labor costs through to higher consumer prices, though wages do not tend to be higher overall in regulated sectors (Hendricks, 1975; Peoples, 1998). In the railroad industry, low regulated profit rates led to underinvestment in track maintenance and repair on many lines, reducing efficiency and increasing average transit time over the track.

Of particular concern is the effect of regulation on the pace of technological innovation. This may occur from direct regulatory constraints on new process or product introductions, such as the Federal Communications Commission's delay in allocating radio spectrum to wireless telephone systems in the USA and its restrictions on enhanced telephone service offerings. Indirect regulatory effects may also influence the pace of technological change by altering expected payoffs to investment in new technology. While often difficult to measure, these costs can be enormous. For example, Hausman estimated lost surplus from the delayed introduction of wireless phone service in the USA at more than $30 billion annually (in Peltzman and Winston, 2000: p. 80).

The ambiguity of cost and innovation effects may arise in part from the difficulty of establishing an appropriate empirical counterfactual benchmark to regulation, an essential prerequisite to measuring either static or dynamic efficiency effects. Nevertheless, ongoing policy concerns about the efficiency of production, investment incentives, and the pace of technological change in natural monopoly sectors have fueled much of the recent movement toward market-based reforms, discussed in Section The Effects of Restructuring Regulated Natural Monopolies.

Empirical Analysis of Regulation in Multifirm Industries

A substantial portion of the regulatory apparatus built during the twentieth century involved multifirm industries, such as trucking, airlines, natural gas and oil production, property and liability insurance, and banking. Regulation in many of these was rationalized by the deleterious effects of excessive, rather than insufficient, competition, particularly during the depression of the 1930s. In others, such as airlines, regulation was advocated to promote the orderly development of an emerging commercial industry. Many of these regulatory systems were dismantled or reformed substantially between 1975 and 1985, reflecting a broad consensus on its social costs.

Multifirm price regulation usually requires all firms serving a given market to adhere to a standard tariff. In some industries, this tariff was set by the regulatory commission, as the Civil Aeronautics Board did for the US airline industry. In others, tariffs were set collectively by the firms and ratified by the regulatory commission, as the Interstate Commerce Commission did for trucking rate bureau filings. Regulation generally discourages entry or market extension. By eliminating the ability of existing firms to discount rates and the ability of new firms to enter the market, regulation limits competition and tends to raise prices significantly. For example, economists estimate that regulated prices in the late 1970s were at least 15–20% above competitive levels in the trucking industry and 25–30% above unregulated prices in the airline industry.

High prices generate significant potential rents. The value of these rents is embodied frequently in the market value of regulatory assets, such as taxicab medallions, operating certificates for regulated trucking firms, or state liquor licenses. Asset values may reflect only a portion of the rents generated by regulation, however. In some sectors, organized labor was able to garnish a substantial share of regulatory rents (Rose, 1987; Peoples, 1998). Members of the Teamsters Union, for example, were a major beneficiary of trucking regulation, with wages 50% above those for nonunion truck drivers and drivers outside the regulated industry. In other industries, regulatory rents were dissipated through various rent-seeking behaviors. This seems to have been particularly acute in the airline industry, where nonprice competition repeatedly eroded load factors and profit margins despite increasing regulated prices. In the rare situations in which regulatory policy effectively constrains maximum prices and exit from markets, rents may be negative. In the short run, this can transfer quasi-rents from owners of regulated capital to consumers of their products. Over the longer run, its adverse effect on investment tends to erode both the quantity and quality of service provided. The rash of bankruptcies in the US railroad industry during the 1970s and early 1980s, and natural gas shortages during periods of below-market ceiling prices in the 1960s and 1970s, were consequences of this type of policy.

As in the natural monopoly sectors, regulation influences the structure of prices as well as the average price level. Economic regulation often leads to a more uniform price structure than in unregulated markets. Prices tend to be less responsive to cost differences across consumers or over time, due in part to cross-subsidies for favored higher-cost consumer groups and to aversion to congestion-based or peak-load pricing. This distorts both capacity utilization and firms' investment incentives. These effects have been analyzed in the context of traffic mix distortions between railroads and trucking firms, provision of air service to small communities, and excessive pooling in insurance markets.

Postderegulation experience suggests that regulation often suppressed variation due to price discrimination, relative to the unregulated market. Airlines are perhaps the best example of this. It is important to recognize that price discrimination, while controversial, may enhance overall welfare relative to a uniform price structure; see the literature on Ramsey–Boiteaux pricing (Kahn, 1988). In airline markets, for example, the pervasive use of low discount fares to fill seats that would otherwise depart vacant increases substantially the population for whom air travel is viable, and raises airline revenue per available seat-mile. The net welfare effect of current levels of price discrimination is difficult to measure, and has not been directly calculated for any deregulated market.

Economic regulation in multifirm industries has been associated with both direct and indirect cost effects. Regulatory restrictions and rigidities may prevent firms from optimizing production in both static and dynamic contexts. For example, entry restrictions in the trucking industry led to high rates of partial or empty backhauls and circuitous routings, raising the

cost of transporting a given commodity flow. Unit banking regulations, which restrict a firm to a single physical location in one state, both limit realizations of economies of scale in provision of service and insulate less efficient banks from takeovers by more efficient competitors. Inefficiencies, such as these generate potentially huge regulatory deadweight losses (Winston, 1998).

The welfare effects of cost increases may be difficult to quantify when associated with offsetting changes in the product provided to consumers. For example, the suppression of price competition may encourage nonprice competition, increasing both costs and quality relative to outcomes in unregulated markets. In the regulated airline industry, increased flight frequency and rapid adoption of new aircraft increased both cost and value to passengers. Measuring cost or productivity effects without controlling for the value of higher service quality leads one to overstate the adverse welfare effects of regulation in situations like this. Recent advances in structural demand estimation may help to quantify the value of particular quality attributes, though both data and modeling limitations continue to make this one of the weaker empirical links in most assessments of the overall effects of regulation.

The Effects of Restructuring Regulated Natural Monopolies

The focus of regulatory policy and research changed sharply in the late 1980s and 1990s, with the ascendancy of market-based institutions over state-ownership and regulation in even traditional 'natural monopoly' sectors. Restructuring, requiring firms to divest along vertical segment lines, has become common. Segments viewed as structurally competitive, such as electricity generation, have been increasingly deregulated. Network segments that continue to operate under natural monopoly cost conditions, such as electricity transmission grids or distribution systems, generally are required to provide access to competitive suppliers, often at terms subject to continued regulatory oversight. Where economic regulation has been retained, it has become more market-oriented. This reflects both dissatisfaction with recent performance under regulation and a response to theoretical research emphasizing attractive properties of incentive-based regulatory schemes (*see* Poverty: Measurement and Analysis).

These changes raise new questions about market design and regulatory interfaces. The emerging empirical literature has focused on three main issues: the impact of privatization, the performance of restructured sectors, and the effects of incentive-based regulation. Policy in this area is very much in flux, as the initial wave of enthusiasm for market solutions confronts unanticipated consequences from their implementation.

The Impact of Privatization

Privatization has been motivated by a range of concerns including the cost of service, pace of technological innovation, and impact of continuing subsidies on government budget deficits. A review of the voluminous literature on privatization is beyond the scope of the present article; see Vickers and Yarrow (1991), La Pörta and López-de-Silanes (1999), and their references. Because privatization has been so closely linked with restructuring and regulatory reform initiatives over the past quarter-century, however, it is useful to highlight key empirical results.

One of the most robust empirical results from this literature is the dramatic impact privatization typically has on cost reduction. This is particularly evident in labor costs. Substantial labor shedding has accompanied privatization almost everywhere, with labor force reductions of 50% or more a common result. Where comparisons with privately owned firms are feasible, studies suggest that postprivatization labor rates approach those at firms that were never government owned. This suggests considerable excess labor in state-owned enterprises. This may reflect the use of state-owned enterprise to promote certain social policies as well as direct operating inefficiencies, suggesting that excess labor costs may include both transfers as well as social deadweight loss.

Privatization often leads to both price and output increases. Rising output despite higher prices suggests the elimination of artificial constraints, such as rationing, or higher quality service for which consumers are willing to pay more. In numerous studies of utility sectors, waiting time for service falls and investment and service quality increase following privatization. This seems most common in sectors that were capital-starved or in which service was underpriced under state-ownership. Even in countries where state-owned utilities were perceived to be functioning relatively well, however, increased investment and innovation may be important benefits of privatization.

One caveat is in order; the frequent concurrence of privatization with changes in the competitive environment can make it difficult to empirically disentangle the relative contributions of ownership change, hard budget constraints, and increased competition to improved performance. Moreover, it appears that the benefits of privatization may be greater when accompanied by increased competition or deregulation. Studies vary considerably in their recognition and successful treatment of this problem.

Performance in Restructured Natural Monopoly Sectors

Vertical restructuring has become common in natural monopoly industries worldwide. In telecommunications, equipment provision and long-distance service were among the first to be carved out of vertically integrated telecommunications firms and opened to competitive suppliers. Power generation has been divested from transmission and distribution functions and opened to competition in many electricity systems. Much of this policy movement appears stimulated by concerns that prices charged by monopoly providers were too high, relative to those attainable by privately owned firms operating in competitive sectors. In some cases, this reflects real operating inefficiencies and reduced innovation under monopoly. In other cases, apparently high prices may in part reflect perverse regulatory pricing schemes. Action on these concerns was facilitated by technological innovations that reduced scale economies at certain production stages and enabled decentralized operations to achieve many of the economies of scope previously attained by vertically integrated firms.

Economists have been especially interested in assessing the competitiveness of restructured markets. Empirical research suggests these markets have yet to converge to competitive ideals. In the US long-distance telephone market, for example, AT&T lost its sanctioned monopoly provider status in 1984, following the earlier technological erosion of its 'natural monopoly.' While long-distance prices have declined, the convergence to competitive norms has been relatively slow, with average per-minute prices more than double estimated long-run incremental costs as late as 1998 (Peltzman and Winston, 2000: p. 77). Some economists have suggested that this reflects relatively weak competition among the small and decreasing number of existing long-distance providers.

Analyses of electricity markets echo this theme. In most restructured electricity markets, unregulated generators bid to supply electricity to the system operator, which determines the dispatch order of generators to supply the electricity demanded at each moment in time. There is considerable evidence of generator market power in many markets, with generators bidding above their marginal generation costs and strategically withholding capacity from the market to increase prices (see Wolfram, 1999; Borenstein et al., 2000; Joskow in Peltzman and Winston, 2000; Joskow and Kahn, 2001).

While many restructured markets have been prone to supracompetitive prices, the extent to which price exceeds cost varies tremendously across different settings. There is growing evidence that performance variations are heavily dependent upon the institutional details of the market's design. These include the way the competitive sector is structured, the terms on which suppliers interface with their customers and the network, and the management of network investments. In electricity markets, for example, the relative sizes of different suppliers, their inframarginal capacity, the use of long-term hedging contracts between generators and their customers, and the degree to which customers see and can respond to real-time price variation have all been demonstrated to influence the exercise of market power.

While competition may enhance cost efficiency in the deregulated sector, restructuring may increase other costs. For example, substitution of market mechanisms for internal decision making or 'command and control' by a vertically integrated firm may increase coordination costs in electricity markets (Joskow in Peltzman and Winston, 2000). In California, for example, reserve margins and hence system operating costs have increased as a result of moving to a dispatch market. Local distribution companies may face difficulties when their requirement to serve, which was imposed in exchange for franchise monopoly in many utility sectors, is maintained, but restructuring eliminates their direct control over electricity supplies, as evidenced by California utilities in 2000–01.

In telecommunications, access issues focus on pricing and interconnection requirements for the 'local loop,' the set of wires connecting individual subscribers to the local network. These problems are magnified by the potential for local exchange carriers to compete with other firms for services beyond the local loop. The determination of access terms has substantial effects for investment incentives by incumbent exchange companies and potential competitors, entry into local, long distance, and enhanced services, and the performance of competitive markets where entry occurs. This is the focus of much current regulatory policy and some empirical analysis (Crandall and Hausman in Peltzman and Winston, 2000).

Effects of Incentive-Based Regulation

While regulatory reform over the past two decades has been substantial, economic regulation continues to play an important role in many sectors. Economic regulation in the new millennium is more market-based than its counterpart of 1970, but less market-driven than current rhetoric would suggest. Policy innovation has been particularly notable outside the USA, perhaps because these systems were being designed *de novo* rather than patched on to existing regulatory practices. Regulation has moved away from traditional rate-of-return regulation, which determined prices through cost-based mark-up rules (Kahn, 1988). More common are higher-powered incentive schemes, such as price caps, which fix price levels or rates of change, and allow firms to keep the surplus generated from unanticipated improvements in efficiency, at least until the next review of the cap or its adjustment factor. The models behind these schemes are discussed elsewhere (*see* Poverty: Measurement and Analysis). It is important to recognize that implementation, however, generally deviates considerably from the theoretical construct.

Many researchers have attempted to measure the impact of incentive-based regulation, particularly in the telecommunications sector. This literature broadly suggests that incentive regulation is accompanied by lower prices. Kridel et al. (1996) suggest that these effects may reflect coincident policies that increase competition more than the incentive effects of incentive regulation itself, however. This interpretation is particularly suggested by the difficulty in finding consistent effects of incentive regulation on costs or productivity, although the short time span of many studies may impede detection of such effects. As earlier empirical work in regulation suggests, one should exercise great caution in affirming the superiority of incentive-based policies based on the theoretical properties of idealized schemes.

Conclusion

The reforms of the 1990s have created a vast new set of institutions and regulatory policies. This is an area in which empirical analysis greatly lags behind the theoretical literature, and the returns to additional careful work are likely to be significant. Empirical research in regulatory economics, argued by some in the 1980s to belong to the domain of economic history, remains vital to guiding, understanding, and evaluating policy initiatives today.

Abstract

Government regulation of firms uses the 'coercive power' of the state to alter firms' pricing, entry, production, investment, and product choice decisions. An extensive empirical literature analyzes the effects of 'economic regulation' of price and entry as well as environmental, health, safety, and information regulation. Results of this work suggest that regulation cannot be understood simply as an efficient intervention to correct market failure. Research on the political economy of regulation seeks instead to understand the origin, structure, and reform of regulatory policy as an outcome of rent-seeking behavior by interest groups mediated through the political process. These models have considerable empirical power in explaining variation in support for particular regulations, but fall short in explaining why some industries are regulated while others are not, and why policy in this area tends to occur in waves.

Government regulation of firms uses the 'coercive power' of the state to alter firms' pricing, entry, production, investment, or product choice decisions. An extensive empirical literature analyzes the effects of 'economic regulation' of price and entry as well as environmental, health, safety, and information regulation. These analyses amassed substantial evidence of high prices, excess profits, and production inefficiencies under economic regulation (see Joskow and Rose, 1989; Joskow and Noll, 1994; and Regulation, Empirical Analysis of). Studies of environmental, health, and safety regulation revealed substantial deviations from least-cost solutions and dramatic variation in measures such as expected cost per life saved across regulatory interventions (see Viscusi, 1994; Gruenspecht and Lave, 1989). These outcomes, so systematic and pervasive, were difficult to reconcile with 'public interest' models of regulatory intervention. Examination of regulatory systems further suggested that they often deviated from cost minimization or efficiency objectives by design. This begged for an explanation beyond bureaucratic incompetence or malfeasance, common to earlier Marxian or 'capture' theories of government. Stigler's (1971) *Economic Theory of Regulation* provided the conceptual underpinnings of what has become a vast enterprise among economists and political scientists to understand the origin, objectives, maintenance, and reversal of regulatory policy in the context of rational choice models of political behavior. These simple insights stimulated a substantial theoretical and empirical literature (Noll, 1989; Peltzman, 1993).

Theories of legislative and bureaucratic behavior have become increasingly sophisticated since the 1980s. The literature has moved well beyond Stigler's simple model to incorporate the role of competing interests, policy entrepreneurs, majoritarian political institutions, legislative oversight of regulatory agencies and commissions, and asymmetric information (see Noll, 1989; Joskow and Noll, 1994; Laffont, 1999, and Regulatory Agencies). The empirical literature has struggled to keep pace with these developments.

Common to virtually all empirical studies in this area is the importance, and difficulty, of defining well-specified alternatives to the political economy model under investigation. To test a given model of political behavior, or to interpret results as consistent with a given model, one must understand how predicted outcomes differ between competing hypotheses of behavior and the model being tested. For example, there is a natural tendency to identify rent conveyance with rent-seeking activity. In some cases, however, increased rents for regulated firms may be consistent with both successful rent-seeking behavior by those firms and elimination of some market inefficiency. It is important, though often quite difficult, for empirical analyses to identify and attempt to distinguish alternatives such as these. Studies vary considerably in the degree to which they meet this standard.

This article introduces the main empirical methodologies used to explore the political economy of economic, environmental, health and safety regulation. Examples of their applications are briefly discussed. Interested readers are urged to pursue the surveys listed in the references for more complete discussions of this literature.

Measuring Distributional Effects

Empirical studies of political economy generally begin with estimates of the distributional effects of a given policy. While many empirical methods may be used (see Joskow and Rose, 1989 and Regulation, Empirical Analysis of), asset market 'event studies' have been particularly popular. These measure price movements in capital assets, such as company share prices, at the time policy changes are first announced. If the announcement is not previously anticipated, and asset markets efficiently process information, these price changes provide estimates of the policy's effect on the capitalized value of expected rent streams. This method may be used to measure the effects of the policy change on firms within a regulated industry, corporate customers and suppliers, and possible competitors. The distributional implications for individual or small business customers, employee groups, and other noncorporate interests usually must be measured using alternative methods.

The simplest political economy studies use measured distributional effects to infer the relative influence of different interest groups in the political process. These implicitly assume that the observed changes in rent distribution are anticipated and intentional, and that larger rent

gains reflect greater political power. Consider, for example, the extensive debate over the origin of the first federal economic regulatory commission in the US, the Interstate Commerce Commission created in 1887 to regulate railroads. Was this legislation intended to solve an inefficiency in an industry characterized by large sunk costs and natural monopoly conditions? If the legislation was a response to interest group politics, did it respond to agrarian interests and other shippers' demands to constrain monopoly pricing by railroads, or was it a railroad-sponsored effort to establish a government-enforced cartel? Did legislation intend one outcome, only to be thwarted by the regulatory agency's subsequent behavior? There have been numerous empirical studies attempting to answer these questions, many using railroad share price responses to various regulatory 'events' (e.g., Prager, 1989; Mullin, 2000). In these, railroad share price gains in response to the Interstate Commerce Act, for example, have been interpreted as evidence that the regulation was intended to benefit railroads, supporting Stiglerian models of regulatory politics. While it may be reasonable to assume that *ex post* gains identify *ex ante* intended beneficiaries, this should be made explicit and considered against alternative explanations. To move convincingly from a positive statement about the distributional consequences of a policy to an inference about its political motivation requires an understanding of distributional effects under leading alternative models.

Estimating Political Support for Regulation

A second empirical methodology estimates the determinants of regulatory incidence or political support as a function of underlying economic interests. These studies generally involve three steps. First, *ex ante* winners and losers of a regulatory policy are identified, using either prior estimates or a model of the regulation's effect. For example, Stigler's (1971) analysis of truck weight laws modeled state truck weight and size limits as raising the cost of trucking service, particularly over longer hauls. Truckers therefore lose from lower limits, as do their current customers, businesses using their own trucks, and potential customers for whom trucking rates constrain alternative transportation rates. Competitors to trucks, such as railroads, gain from tighter restrictions. There may be diffuse 'public interests' as well, for example, in limiting damage to roadbeds and reducing congestion, though these may well be endogenous.

Second, the importance of the identified economic interests within a given jurisdiction or at a particular point in time is measured. There is considerable variation in how this is done. For example, the number of trucks, scaled or unscaled, the dollar volume of activity in trucking, and the fraction of freight hauls susceptible to potential truck competition are all possible measures of the importance of trucking interests in a jurisdiction.

Finally, the incidence or intensity of regulation, or the political support for regulation, is estimated to be a function of the measured economic interests and any other relevant factors. Stigler used this method to explain differences in the intensity of truck weight limitations across states, for example. Other studies apply this technique to model variation in political support, such as voting records, as a function of constituent economic interests in the policy, *inter alia*.

Most studies in this area find that constituent interests are significant determinants of regulatory policy, though interests must be defined broadly to include constituent preferences (such as conservation or environmental preferences) as well as direct economic interests. Detailed studies of voting behavior suggest that the underlying models may be quite complex, however; see, for example, Joskow and Schmalensee (1998) on the US acid rain program. The significant impact of legislators' ideology on their voting behavior (e.g., Kalt and Zupan, 1984) suggests possible slack in the agency relationship between constituents and their legislators, as well support for more sophisticated models of voting in majoritarian systems across issues and over time.

Modeling Regulatory Agency Behavior

A final strand of empirical work in political economy begins with the recognition that most regulatory legislation leaves considerable discretion over its implementation to regulatory agencies or commissions. Early work on regulatory 'capture' assumed that industry groups could influence regulators to use this discretion to benefit the industry in direct contravention to legislative intent. As economists and political scientists began to explore the extent to which apparent regulatory capture was instead a reflection of legislative intent, they confronted the questions of how much discretion regulators retain and how regulators use that discretion to form policy (e.g., McCubbins et al., 1987). This led to an extensive literature on the operation and oversight of the administrative process, most of it within political science. This area remains one of the least-developed empirical literatures in regulatory economics.

While some early analyses explored the responsiveness of regulatory agency decision-making to congressional preferences, most economics research in this area analyzes the responsiveness of agency decision-making to interest groups and various measures of efficiency or social welfare. This is methodologically quite similar to the legislative studies described in Section Estimating Political Support for Regulation, with individual regulatory decisions as the unit of observation. As in those studies, the results suggest a role for concentrated economic interests to influence regulatory outcomes. This does not itself demonstrate that regulators respond to interest groups in contravention with broader social objectives, however. For example, studies have found that despite significant overall delays in the process by which the Food and Drug Administration (FDA) controls entry of new pharmaceutical products, the FDA responds more quickly to drugs with greater market potential (Dranove and Meltzer, 1994). In this case, both producer and social interests are aligned with reducing delay of an innovation.

Conclusion

While research on the political economy of regulation has made significant progress since the 1970s, fundamental

questions remain unanswered by either theoretical or empirical work (Peltzman, 1993; Joskow and Noll, 1994). One of the most basic is why some industries are regulated (or deregulated) and others are not. Another is why regulatory policy seems characterized by 'waves' or cycles: changes tend to occur across broad ranges of industries and sectors within fairly short periods, separated by longer periods of relative inactivity. Considerable scope remains for additional work in this area.

Regulatory Agencies

Abstract

The term 'regulatory agency' is attached mainly to administrative entities intended to monitor and influence business activity in response to varieties of market failure. Observers have undertaken four general lines of inquiry into, and commentary about, such agencies: (1) creation dynamics, (2) types and tactics of influence by governmental principals and by attentive nongovernmental players, (3) circumstances that may undermine agency existence, and (4) how well regulatory agencies serve their assigned purposes. The United States and Europe manifest significant similarities and differences.

Broadly defined, regulation includes any governmental effort to control behavior by other entities, such as business firms, subordinate levels of government, nonstate entities (such as political campaigns or civil society actors), or individuals. Sovereign governments may cooperate under regimes of mutual constraint that yield rules or decisions characterized as regulations. Most political and scholarly discourse on regulation addresses programs or policies intended to monitor and restrict commercial activity. Regulatory agencies are, generally speaking, those public entities holding delegated authority to implement such programs and policies.

Persons not thoroughly familiar with comparative regulatory policy are cautioned regarding important, and potentially confusing, differences in terminology between the United States and Europe. The terms 'regulation,' 'directive,' and 'decision' are not synonyms in European Union (EU) parlance where each has a distinctive connotation and is regularly described as a type of 'legislation' (see e.g., http://ec.europa.eu/legislation/index_en.htm). In the United States, one never describes the national bicameral Congress as in itself a 'regulatory agency' but rather as a legislative body that authorizes, appropriates funding, for and oversees activity within such agencies. In the EU, a 'regulation' is 'similar to a national law with the difference that it is applicable within all EU countries,' while a 'directive' establishes 'general rules to be transferred into national law by each country' and a 'decision' addresses 'a particular issue and specifically mentioned persons or organizations.'

Within business regulation in the United States four primary types may be distinguished (Breyer, 1982). First, regulation may control market entry (as with occupational licensing or air carrier certification). Second, it may (as in the case of electric utilities and other 'natural monopolies') establish directly the prices that firms can charge customers. Third, it may limit the competitive practices available to firms, especially as regards price setting (e.g., the law of antitrust), advertising, and disclosure. Fourth, regulation may aim to improve and standardize (through industry-wide rules, inspection regimes, or premarket approval processes – e.g., commercial pharmaceuticals) the quality of specific work practices or products, often to protect human health and safety or the environment. The first and fourth types may overlap in practice; carrier certification, for example, necessarily creates entry barriers in the service of air safety. These four types are sometimes subsumed under two more general headings: 'economic' (i.e., price, entry, and competitive practices) and 'social' (meaning generally health, safety, and environmental) controls. More refined policy rationales for each type of regulation, broadly described as varieties of 'market failure' (e.g., curbing monopoly and cartel power, moral hazard, planning on behalf of future needs, imperfect and asymmetric information, provision of public goods, control of negative externalities) may be identified (Baldwin and Cave, 2012).

Social scientists and historians have posed three primary empirical questions about regulatory programs. First, what forces lead to their creation (Kolko, 1965; Wilson, 1980)? Second, political scientists and economists have asked what factors influence agencies, prompted by a desire to fix more precisely, in the face of governmental fragmentation, the true institutional locus of political control over policy-relevant behavior by agencies (Wood, 1988; Moe, 1982, 1985) or the precise role of supervisory tools such as budgets (Carpenter, 1996) or legislative oversight and procedural constraints (McCubbins et al., 1987)? Third, given the inertial forces that regularly contribute to the durability of many public programs (i.e., combinations of concentrated support, diffuse criticism, and widespread indifference) under what conditions may regulatory programs be scaled back or terminated (Derthick and Quirk, 1985)?

Normative questions also proliferate. Much business regulation, especially in the United States, has been prone to intense controversy. Both business representatives and policy-focused academics have pursued long-running debates about the merits of various regulatory programs, the quality of their specific decisions, and reforms to enhance accountability, independence, expertise, administrative efficiency, and sensitivity to the costs that regulation imposes on specific business sectors and on society generally. With the creation and evolution of the EU arose inevitable questions of the correct balance to be struck among a plethora of public values, including the tension between established national preferences and practices on the one hand and the need for effective supranational coordination and consistency on the other (Gerardin et al., 2005).

Empirical Inquiry

Students of regulation have long found the formally stated public goals of regulation inadequate to explain program creation and maintenance. From the 1950s to the 1970s, working within such disciplines as economics, political science, and historical analysis, commentators viewed regulatory programs frequently as being prone to 'capture' by regulated interests (Huntington, 1952; Bernstein, 1955; Kolko, 1965; Stigler, 1971). By some accounts, regulation was said to have arisen because a diffuse majority favoring regulation (and motivated by a 'public interest' rationale, such as the elimination of predatory pricing or consumer fraud) succeeded, at least briefly, in obtaining legislative consensus, often in the wake of well-publicized scandal. Over time, however, according to this 'life cycle theory' of regulation posited by Bernstein (1955), waning public attention and media scrutiny was said to have allowed resourceful regulated interests, whose attention to regulatory program activity did not wane, to exercise a strong (even dominant) influence over the program, thus thwarting its original intent.

A different version of capture analysis suggested that such programs were sometimes created, at least partially, at the behest of economic interests, perhaps as an exercise in 'rent-seeking' behavior (Dudley and Brito, 2012). Agencies might thus, in effect, be 'born captured' due to business incentives to seek stable and reliably profitable operating environments. The capture model of regulation is in some respects akin to a traditional political science metaphor, widely employed during the same period, describing the politics of narrowly distributive public policies in terms of 'iron triangles' composed of interest groups, legislative committees, and agencies. The similarity is striking, even though an analytic scheme widely appropriated among political scientists (Lowi, 1964) highlighted a distinction between 'distributive' and 'regulatory' politics. From the 1970s onward, however, scholars of public policy challenged increasingly the descriptive accuracy of the 'capture' and 'iron triangle' metaphors (Heclo, 1978; Wilson, 1989).

In the United States especially, this challenge stemmed importantly from the creation of regulatory programs (e.g., in environmental, consumer, and worker protection) where lack of media scrutiny, public indifference, and business dominance plainly did not apply over the long run (Wilson, 1980). The 1960s and the 1970s were notable (Sunstein, 1990) for a number of "bold regulatory initiatives in a number of new areas" (p. 25). Indeed, the creation of these programs often represented sustained triumphs by idea-driven policy entrepreneurs over business interests that had to adjust to the presence of long-term political competitors. In one prominent instance, the regulation of nuclear power generation, a policy milieu changed dramatically from one to which the term 'capture' could arguably have applied in the 1950s. By the 1990s, the politics of nuclear power in the United States had evolved into a far more complicated set of power relations, in which environmental advocates and citizen groups competed more effectively with the nuclear industry (Duffy, 1997).

Throughout the 1980s, political science commented increasingly about the inadequacy of simple generalizations regarding regulatory politics as a whole. The concentration of costs and benefits prevailing in regulation were found to differ importantly among agencies, and across issues within a single agency (Wilson, 1980). The politics of broadcast regulation, pursued within a markedly vague standard of 'public interest, convenience, and necessity,' clearly varied between technical industry structure matters and issues of program content (Krasnow et al., 1982). Within public utility regulation, issues were determined to differ in complexity and conflict, with significant implications for the power of different kinds of advocates (Gormley, 1983), and the characteristics of commission personnel were also found to vary in ways important to generating distinctive regulatory outputs (Berry, 1984). Moe (1985) found decision making by the National Labor Relations Board to stem from quite complex causal influences including an array of external and internal institutional actors and exogenous conditions.

Regulatory policy became the staging ground for scholarly argument over the relative independence of agencies. A conventional position among journalists and political scientists had for many years held that Congress did little to oversee bureaucratic behavior, largely because of the modest political incentives said to prevail. In arguing against what he called 'interest group liberalism,' Lowi (1969) bemoaned the vagueness that had crept into legislative delegations for regulatory and other programs. A later principal-agent perspective on the legislative–executive relationship argued for the existence of a more robust oversight mechanism grounded in a rational legislative approach to structure and procedure that appeared superficially to be weak, a system that, paradoxically, worked precisely by appearing to have failed (McCubbins and Schwartz, 1984). Examination of agency case histories determined that widely trumpeted accusations of 'runaway bureaucracy' often directed at regulation were misplaced (Foreman, 1988).

The classic political science question 'who governs?' (Dahl, 1961) has been answered repeatedly over many years for regulatory agencies in numerous ways by observers employing various methods and intellectual vantage points. Because regulation is politically contentious and generates substantial numbers of comparable implementation and enforcement decisions over time, political scientists (often working within the tradition of rational choice models and principal-agent theory) have gravitated to regulation as a window on relative institutional influence more generally. Some analysts have emphasized the power of legislative principals (activated by the material stakes of affected parties) over agency behavior (Weingast and Moran, 1983; Weingast, 1984). Moe (1982), examining time series data drawn from three US regulatory commissions concluded that presidential power deserved emphasis. On the other hand, some analysts have looked inside regulatory bureaucracies to the professional worldviews and incentives of staff members as key drivers of agency behavior. In antitrust enforcement, economists and attorneys are among those professionals whose views have been found to have a profound impact on agencies, both in case studies (Katzmann, 1980; Weaver, 1977) and in quantitative analysis (Eisner and Meier, 1990). The theory of 'overhead democracy' embraced by Wood and Anderson (1993) ascribed variation in both the level and substance

of antitrust regulation to a complex set of institutional forces; changing presidential administrations, congressional committee preferences, and court decisions all helped to mold antitrust activity.

The US Food and Drug Administration (FDA), responsible for premarketing the clearance of drugs and medical devices as well as scrutiny of the food supply (save meat, eggs, and poultry, which fall under the purview of the US Department of Agriculture) epitomizes the diversity of considered views that have evolved regarding power relations. Shipan (2004) develops a spatial model of political oversight, applies it to FDA, and finds that the degree and locus of legislative influence varies, with the agency acting autonomously in some instances. Carpenter (2001, 2010) has emphasized agency 'reputation' and executive entrepreneurship as the major drivers of substantial bureaucratic autonomy in both the FDA and other administrative contexts. Alternatively, observers beyond political science often appear more wary of corporate influence in the FDA's political environment (Hilts, 2003; Nestle, 2002). Both mocked by business-friendly politicians as the supreme 'job killer' in the United States (Carpenter, 2010: p. 731) and challenged by consumer activists and environmental enthusiasts to strive ever harder on behalf of the public's health and safety, the FDA is inherently controversy prone.

Deregulation is rarer, and politically more problematic, than regulatory initiatives. As regards social regulation, such goals as a clean environment, and safe workplaces and pharmaceutical products, are popular with the public. In economic regulation, organized stakeholders would be expected to resist unfavorable change (i.e., alteration of profitable regulated environments). Given such forces, it is worth emphasizing that deregulation has occurred on occasion, and asking how this has come about. Derthick and Quirk (1985) point to the power of ideas and effective leadership. They observe that, by the late 1970s, economists had mounted a sustained, coherent, and nearly unanimous attack on the underlying justifications for price and entry regulation in the transportation sector. This procompetition critique gained added political impetus from the increasing visibility of economists in national policy debates, from the infiltration of economists into leadership of the regulatory apparatus, and from the transformation of deregulation into an antiinflation and consumerist cause that both liberals and conservatives could support. Strong presidential and legislative leadership also proved to be pivotal. One dramatic result was the phased legislative elimination, culminating in 1984, of the Civil Aeronautics Board, which had, since the 1930s, managed pricing and entry for commercial interstate aviation in the United States.

Normative Assessments

Regulatory programs regularly inspire supporters and detractors in the social sciences on grounds of efficiency (whether administrative or economic), equity, and democratic accountability. Even Sunstein (1990), a strong academic defender of regulation (who would also serve as top regulatory policy reviewer for a US president) acknowledges many ways that regulation may fail. Unlike price and entry regulation, which regularly has found advocates of abolition in the economics profession, other types of regulation enjoy strong academic support on principle (e.g., recognition of 'market failure'), though often not in specific detail. Leading the charge for varieties of regulatory reform have been economics-oriented analysts associated with policy research institutions or 'think tanks.' Criticisms of environmental policy stress varieties of putative inefficiency or irrationality. For many years, critics have argued that costs often exceed benefits, are higher than necessary to achieve a given level of environmental benefit, and perhaps are masked altogether by inadequate economic analysis (Kraft, 1996: pp. 165–166; Litan and Nordhaus, 1983; Lave, 1981). Inefficiency is sometimes argued to have been caused by the logic of political compromise (Ackerman and Hassler, 1981) or by unwillingness to impose overtly visible losses on large numbers of voters (Nivola and Crandall, 1995). Inadequate monitoring has long been said to bedevil the assessment of pollution control efficacy (Crandall, 1983; Davies and Mazurek, 1998). A broader, efficiency-based critique encompasses additional concerns, including the discordant, meandering, and arguably panic-stricken character of regulatory politics and policy (Breyer, 1993). Critics point to a chronic inability to set risk priorities, to confront risk–benefit and risk–risk trade-offs (Graham and Wiener, 1995), and to reconsider regulatory statutes in the light of such concerns.

Especially in the United States support for risk assessment and cost–benefit analysis have in recent decades somewhat displaced precautionary 'zero-risk' stances in regulatory reform. The Delaney Clause enacted in the US Food, Drug, and Cosmetic Act in 1958, one of the earliest and best-known examples of the zero-risk mind-set, held any food additive intolerable in any amount in the food supply if determined by any study to cause cancer in humans or animals (Vogel, 2012). After many years of discrediting criticism, the provision was finally replaced in food safety law in 1996 by a standard of 'reasonable certainty of no harm.' Moreover, US presidents of both parties since the early 1970s, and especially since the Reagan era, have embraced formal and centralized regulatory review processes – note Sunstein's role alluded to above – grounded in cost–benefit and cost-effectiveness analyses.

In a quite different vein, however, environmental, agricultural, energy, and other related policies (and thus the regulatory agencies central to forging and implementing them) have encountered varieties of 'grassroots' community mobilization and critical advocacy, creating an evolving discourse, simultaneously scholarly and public, under such equity-centered rubrics as 'environmental justice' (Foreman, 1998; Shrader-Frechette, 2005), 'food justice' (Gottlieb and Joshi, 2010), and 'climate justice' (Posner and Weisbach, 2010; Tokar, 2010). These framing rubrics emphasize that low-income communities in the industrial West, and the global poor generally, face disproportionate negative externalities, and enjoy less-than-commensurate gain, from many commercial pursuits. Such insurgent activist-generated frames naturally challenge established regulatory agency mandates and cultures. They also often depart from a 'disinterested politics' grounded in scientific rationality and formalized risk assessment in favor of the presumed 'experiential knowledge'

of health impacts associated with residence in a particular locale (Tesh, 2000). Overall, these competing discourses regularly exhibit considerable polarization, with efficiency-based arguments generally finding little support among the champions of such equity-based critiques, and vice versa.

The sheer inability of regulation to keep pace with the innovation it purportedly oversees is a common criticism. Pharmaceuticals and toxic chemicals have long been targets of concern. More recently, the global Great Recession triggered by a series of financial shocks in the market for an array of underregulated (and often poorly understood) financial instruments produced significant (if to many observers problematic) new regulatory legislation in the United States. It also led political scientists to diagnose a systemic problem of 'political bubbles' (grounded in combinations of ideology, interest, and institutional forces) that promote, rather than curb, a damaging inclination to speculative frenzies (McCarty et al., 2013). Buiter (2008) suggests the term 'cognitive regulatory capture' as applying to the relationship between Wall Street and the US Federal Reserve in the period leading up to the Great Recession.

International and Comparative Perspectives

All developed nations regulate but vary substantially in both regulatory structure and regulatory political culture. The United States has often been portrayed as having a markedly more adversarial and legalistic system than other countries (Kagan, 2003). One study concluded that while "regulatory power has been directed at very similar ends (i.e., control of carcinogens)" in Britain, France, Germany, and the United States, "the openness, complexity and divisiveness of American decision making have no parallel in Europe" (Brickman et al., 1985: pp. 301–302). It is not clear, however, that the American style of regulation is necessarily more stringent than that of other nations. Conceding the more open regulatory style of the United States in comparison with Canada, Harrison and Hoberg (1994), nevertheless, do not find the latter consistently less stringent than the former.

The most up-to-date and wide-ranging comparison of health, safety, and environmental regulation in the United States and Europe (Vogel, 2012) argues that, since about 1990, the EU has embarked on a path of notably more stringent regulation than the United States in such areas as chemical hazards, greenhouse gas emissions, cosmetics, and various areas of food safety including hormone-treated beef, antibiotics in animal feed, and genetically modified organisms. The United States has in recent years retreated considerably from its former inclination to embrace the 'precautionary principle' (holding that a product or process should not be deemed safe until demonstrated to be so) and instead elevated risk assessment and cost–benefit analysis as regulatory decision tools. Europe, on the other hand, has moved in a very different direction, explicitly privileging precautionary thinking and acceding to the demands of member governments, nongovernmental organizations (NGOs), and popular sentiment in favor of regulatory stringency. The key supranational regulatory agency of the EU, the European Commission, wielding powers of both policy initiation and executive implementation, and "where most European legislation is drafted before being submitted to the Council of Ministers and the European Parliament" has been proved to be especially open to "the expertise of environmental NGOs in formulating and drafting new regulatory proposals" (Vogel: p. 245).

Lacking both the heritage of nationalized industry and the stronger commitment to welfare state provision common in Europe, it was perhaps natural that the United States would sooner and more strongly adhere to a path of regulatory agency policing of the private sector. Thatcher (2005) observes that historically "very few [independent regulatory agencies] existed in Europe – they were very much an American institution" (p. 50). However, in the years since the formal creation of the EU in 1993, the continent has increasingly been described in terms of a 'regulatory state' (Majone, 1996). Ambition to create a single European market, manifest in the 1957 Treaty of Rome (and superseded most recently by the 2009 Treaty of Lisbon) necessitated, through regulatory innovation, the elimination of barriers to economic exchange among member nations, though this was impeded by "a proliferation of national rules as the member states increasingly adopted national measures to protect their industries and to respond to new concerns about consumer and environmental protection in the late 1970s and early 1980s" (Young, 2005: p. 96). Even today the emergence and continued strengthening of the EU has not obliterated national variation and vested interests. Though notably more resistant overall to genetically modified organisms than the United States, the political efficacy of opponents varies among European nations and can be blunted by a strong biotechnology sector (Kurzer and Cooper, 2007). Commission efforts to pursue tobacco advertising regulation prompted intense and long-running disagreement grounded in varying national policy outlooks (Duina and Kurzer, 2004). In telecommunications, the Commission, "mainly because of opposition from regulators in the EU member states, tried but failed to create an EU agency" but succeeded in aviation safety (Levi-Faur, 2011). Indeed, channels of consultation and cooperation (formal and informal) among the key EU institutions, an array of nongovernmental interests, and the European member governments are pervasive with policy results varying across regulatory issues and sectors.

Observers of the European regulatory milieu commonly point to its proclivity toward "a particularly intense form of multilateralism" and western Europe's "apparent predisposition to engage in cross-border regime building" as driven significantly by "specific features of history and geography" [and]… "a political culture of investing in institutionalized cooperation with neighbors and partners, at least in the period since the second world war" (Wallace et al., 2005: p. 5). Multilateral regulatory policy innovation has faced much rougher sledding in the United States. Vogel (2012: p. 6) notes that while "every major environmental agreement supported by the United States has been ratified by the member states of the EU and/or the EU itself, since the early 1990s the United States has not ratified twelve important international environmental agreements ratified by the EU and/or it members states."

Globalization has also prompted a major voluntary firm-level effort to promote harmonization under the ISO 14001 framework. This establishes criteria by which a firm or an organization may seek certification for its 'environmental management system' (Delmas, 2004). Hence, governmental regulatory agency mandates are by no means the sole formal mechanism for attempting to create incentives and processes supportive of a significant category of regulatory policy goals.

Strong divisions of formal authority among sovereign national and subnational governmental layers found in the United States have no exact analog in the EU context (or in most others for that matter), although diffusion of responsibility and significant informal interaction characterize both regimes. The EU maintains a legislative arrangement embracing (at the time of this writing) a 766-member popularly elected European Parliament, a 28-seat Council of the EU (also known as the Council of Ministers) representing member states, and a 28-seat European Commission charged with initiating legislation. America's bicameralism is only broadly similar with a 100-seat Senate (each state represented by two popularly elected senators) and 435-seat House of Representatives, a structure recognizably mirrored in all but one of its 50 subnational state legislatures (i.e., the unicameral exception of Nebraska). The United States and the EU are alike, however, in their respective pursuits of democratic management and oversight of the use of authority delegated to agencies with varying regulatory mandates and degrees of independence.

Rehabilitation (Cardiac): Psychosocial Aspects

Abstract

Cardiac rehabilitation (CR) is a clinical intervention aimed at improving the health and well-being of people with cardiac disease. CR programs combine key components of exercise, education, behavior change, and psychosocial support. An overview of the influence of major psychosocial factors on people's recovery is provided. Despite overwhelming evidence of the effectiveness of CR, uptake and adherence still remains low. A better understanding of both patterns of attendance and predictors of noncompletion and nonattendance are required to inform interventions to increase uptake of CR and maintain or improve the adherence of people with long-term cardiac conditions.

Background

Cardiovascular disease (CVD) remains the leading cause of mortality in many industrialized countries, including North America, Europe, and the UK (WHO, 2011). Improvements in acute and longer-term clinical management have increased the numbers of patients surviving cardiac events. Within the UK, an estimated 2.5 million people live with coronary heart disease (CHD) generating health care costs in the region of £1.8 billion in 2009 in the UK alone (British Heart Foundation (BHF), 2012).

Cardiac rehabilitation (CR) is a clinical and cost-effective intervention, routinely offered to patients following hospital admission with acute coronary syndrome (ACS). ACS is a term used to describe acute myocardial infarction (MI) and unstable angina. The primary aim of CR is to improve the health and well-being of people who have heart problems such as ACS to allow a return to premorbid levels of function. Behavioral change, a key element of CR, aims to promote improved diet, to reduce smoking, and to increase activity levels in order to reduce the risk of recurrent cardiac events.

Cardiac rehabilitation is defined as:

> The coordinated sum of activities required to influence favorably the underlying cause of cardiovascular disease, as well as to provide the best possible physical, metal and social conditions, so that the patients may, by their own efforts, preserve or resume optimal functioning in their community and through improved health behavior, slow or reverse progression of disease.
>
> (British Association for Cardiovascular Prevention and Rehabilitation (BACPR), 2012: p. 2)

CR may be offered in a range of forms, delivered in health care, community, or home-based settings. CR programs, once exclusively exercise based, are now more comprehensive combining the key components of exercise, education, behavior change, and other psychosocial support interventions. CR is increasingly tailored and delivered to meet individual need (Heran et al., 2011). CR forms part of an integrated cardiology service that positively influences patient participation, adherence, and long-term behavior change and is an obligatory element of any cardiovascular health care service (BACPR, 2012).

Current CR provision is delivered in the context of a dynamic clinical environment. Diagnostic definitions have changed with the use of new highly sensitive and specific biomarkers. Early interventional procedures, integral to medical management, have led to very short periods of hospitalization. Early discharge results in limited time for patients to adjust to their cardiac event. Changing demographic profiles also mean patients may be older with more complex comorbidities, therefore CR needs to be further tailored and to be sufficiently accessible to meet the needs of these individuals.

Development of Cardiac Rehabilitation

Early CR programs developed in the 1960s targeted patients following MI or cardiac surgery were mainly exercise based but have since been expanded to include cardiac patients with angina, heart failure, postintervention, and following device implantation (BACPR, 2012). Current more comprehensive menu-based programs including educational, exercise, psychosocial components as well as health-related behavior change strategies have been developed in response to an increased understanding of key issues including the underlying pathophysiology, traditional risk factors such as smoking, poor diet, physical inactivity, and more recently important psychological determinants, such as anxiety, depression, anger, and misconceptions regarding coronary heart disease.

Education is an essential component of CR, designed both to address misconceptions about ACS or CR itself (French et al., 2006) and to facilitate patients to make informed choices about their ongoing management. Education is critical to the development of improved patient understanding regarding issues surrounding risk factor reduction and is essential in improving patient reports of perceived personal control and facilitating confidence in managing their cardiac condition (BACPR, 2012).

Given the complexity of patients' needs and the potential variation in modes of delivery of CR programs there is currently no standard CR program. There is a move away from the provision of CR in distinct phases or stages to the design and delivery of individualized programs that meet patient needs from the point of the acute event and thereafter within their long-term care. While exercise continues to be a core component of CR there is significant variation in service provision. In the US, an outpatient CR program typically consists of 36 sessions, with 2–3 per week over 12–18 weeks (Oldridge, 2012). In contrast, many UK outpatient programs start around 4–6 weeks following discharge and are offered once to twice weekly over 8–12 weeks. Patient journeys through CR are increasingly individualized and based upon needs assessment, making comparisons between CR in settings and within patients difficult.

Alternative, effective models of CR have been developed that support patients in remote and rural settings, or to support those who prefer not to participate in-group sessions (Higgins et al., 2005). More recent developments include the use of cellular Web-based electronic service delivery further extending the reach of such CR services and increasingly allowing remote telemonitoring of patient symptoms and interactive support of progress (Neubeck et al., 2009; Varnfield et al., 2011). Home-based programs, often based on standardized manuals such as the Heart Manual show comparative psychological benefit compared with hospital-based programs (Lacey et al., 2004). The primary advantage of home-based programs relate to improved access. Otherwise, the effects are similar on cardiac risk factors, health-related quality of life (HRQoL), mortality, and clinical events.

Risk Factor Reduction: Life Style and Behavioral Risk

The individual and synergistic roles of cardiovascular risk factors including smoking, poor diet, increased cholesterol, obesity, and physical inactivity in the development of cardiac disease are well recognized. The prevalence of each of these risk factors can be influenced by age, sex, socioeconomic status, ethnicity, and geographical region (BHF, 2012).

Psychoeducational interventions in CR have been used to reduce conventional risk factors, many of which are related to behavior, including elevated blood pressure, raised blood cholesterol levels, overweight, obesity, and diabetes (Whalley et al., 2011). Health behavior change is central to CR, and may be facilitated by the use of motivational interviewing, relapse prevention strategies, goal setting and pacing techniques, as well as offering partner support (Moser and Dracup, 2004). CR programs develop and apply tailored lifestyle risk factor management plans following comprehensive assessment of a range of lifestyle behaviors. The positive benefits of increasing physical exercise and activity levels, in combination with a healthy, cardioprotective, Mediterranean style diet have been established in terms of weight management and avoiding obesity (NICE, 2007). Health behavior change targeting smoking cessation, alcohol reduction, and relapse prevention are now part of UK CR standards (BACPR, 2012). Taxonomies of behavior change techniques have been developed in areas of physical activity, eating, and in smoking (Michie et al., 2011).

Psychosocial Determinants and Impact on CHD

More recently, the role of psychological factors, such as anxiety, depression, and anger have been recognized as independent risk factors in the development and maintenance of chronic disease (Khayyam-Nekouei et al., 2013; Suls, 2013). Cardiac misconceptions, illness, and treatment beliefs may also influence recovery and outcome (French et al., 2006; Furze et al., 2005). The psychosocial elements of CR include the assessment and management of emotion and mood, including anxiety, depression, and anger. Specific illness perceptions, perceptions of social support, self-efficacy, and outcome expectancy beliefs regarding treatment can support behavioral change (BACPR, 2012).

Anxiety and Depression

Depressed patients are 64% more likely to develop ACS (Lett et al., 2004) and to recover less well in the short and longer term (Barth et al., 2004). Development of depression following a cardiac event has been associated with an increase in serious subsequent cardiac events (Dickens et al., 2008), more frequent hospital admissions, and an increase in all-cause morbidity and cardiac mortality (Barth et al., 2004; Connerney et al., 2010).

The presence of both anxiety and depression in cardiac patients may be the result of a reaction to hospitalization, the disease itself, or may represent an underlying chronic condition (Kornerup et al., 2011). The prevalence of anxiety in cardiac patients has been found to be as high as 32% (Kornerup et al., 2011) and significant levels of anxiety and depression may persist up to 12 months post-ACS event (Thombs et al., 2006). Anxious patients have a 36% increased risk of adverse cardiovascular outcome compared with nonanxious patients (Roest et al., 2010). However, studies comparing anxiety and clinical endpoints such as MI and cardiovascular death do not show consistent results. For example, the likelihood of an ACS patient having a further event in a 5-year follow-up is not associated with anxiety or depression measured at either baseline or 1 year (Kornerup et al., 2011).

Anger and Hostility

While studies such as the Recurrent Coronary Prevention Project (Friedman et al., 1986) show that reductions in Type A behavior (i.e., individuals that are impatient, ambitious, highly status-conscious, sensitive, rigidly organized) lead to lower rates of recurrent MI, anger, and hostility are now thought to be a more reliable predictor of CVD. Anger and related emotions are associated with increased prevalence of CVD, subclinical disease, and life-threatening arrhythmias (Suls, 2013). Patients with high hostility scores are up to 2.5 times more likely to have restenosis following angioplasty (Kuper et al., 2002). Few intervention studies exist targeting anger in cardiac patients and their results are unequivocal (Suls, 2013).

Misconceptions, Illness Beliefs, and Self-Efficacy

Cardiac misconceptions are erroneous beliefs about heart disease, often associated with maladaptive coping strategies,

which may provoke anxiety (Furze et al., 2005; Roesch and Weiner, 2001) and negatively influence a person's decision to adopt or reject lifestyle modification to reduce future coronary risk (Darr et al., 2008). Misconceptions can negatively influence treatment adherence, attendance at CR, mood, physical functioning, HRQoL, and return to work, and can lead to more admissions to hospital (Le Grande et al., 2012). A systematic review (French et al., 2001) found that participants reported stress to be the most important cause for CHD in 41% of studies, rather than classical risk factors of lifestyle behaviors, which were cited as principal source in only 31% of studies. This lack of concordance between patients' actual coronary risk factors and their causal attributions for CHD is commonly reported (Astin and Jones, 2004). Misconceptions are also reported by peers and family members (Roebuck et al., 2001) resulting in unhelpful behaviors such as over protection (Roebuck et al., 2001). Clinical staffs who hold erroneous beliefs may also offer inappropriate advice for recovery, perhaps inadvertently influencing patients to adopt avoidant behaviors and sedentary lifestyles following their acute event (Lin et al., 2008).

Patient beliefs about their illness may also influence coping, subsequent behavior, and cardiovascular outcome (Hagger and Orbell, 2003). For example, patients who believe that their illness was controllable at the time of their cardiac event report high self-efficacy in their ability to maintain exercise 3 years later (Lau-Walker, 2007). Patients with acute MI tend to perceive their condition to have less severe consequences than those with heart failure (HF). MI patients report shorter duration (timeline) and lower identity scores than HF or angina patients (Le Grande et al., 2012). This may reflect patient underestimation of the severity of their condition and the future effects of their illness. Early intervention procedures such as angioplasty, a shorter hospital stay coupled with patient anxiety, may negatively impact on information retention and patient recovery (Rushford et al., 2007).

Changes from an acute to a more chronic perception of illness in patients post-MI is likely to result in decreased personal and treatment control beliefs and is associated with increased fatigue and poorer HRQoL (Alsén et al., 2010). While multifaceted interventions combining motivational interviewing techniques with cognitive behavior therapy (CBT) may change maladaptive beliefs significantly and positively (Lau-Walker, 2007), the effects of these changes on behavioral, psychological, and functional outcomes require further investigation (Goulding et al., 2010).

Cardiac Rehabilitation: Is It Effective?

There is strong, consistent, and positive evidence from systematic reviews and meta-analyses of randomized controlled trials that comprehensive CR programs facilitate physical and psychological recovery following acute cardiac events (Oldridge, 2012).

Morbidity and Mortality

Cardiac rehabilitation is associated with a reduction of cardiac mortality by 26% and all-cause mortality by 13–26% (Heran et al., 2011; Lawler et al., 2011; Taylor et al., 2004; Oldridge, 2012). Only 86 patients need to be treated to achieve benefit in all-cause mortality, and even fewer, 37 patients, to achieve these gains in cardiac mortality (Oldridge, 2012). CR also leads to a 38% reduction in nonfatal MI (Clark et al., 2005) as well as to a 28–56% decrease in unplanned readmissions (Davies et al., 2010a), thus yielding significant cost savings. Patients who participate in CR are up to 3 times less likely to die or have a further cardiac event as compared to those who do not participate (Chow et al., 2010; Hammill et al., 2010).

Life Style and Behavioral Risk

The modification of cardiovascular risk and adherence to lifestyle change during CR, combining a healthy diet, physical exercise, weight management with the avoidance of obesity and smoking is associated with improvement in cardiovascular health and all-cause mortality (Chow et al., 2010). Attending CR also positively influences functional capacity and the development of self-management skills supporting an early return to work (Yohannes et al., 2010).

Brief interventions designed to motivate lifestyle change can also have a modest positive effect (Fernandez et al., 2007). Short-term programs supported by CBT-based interventions targeting negative emotions, feelings, and cardiac misconceptions, enhancing self-management and self-regulatory processes (i.e., goal setting) have reduced cardiovascular risk and increased physical activity at 6-month follow-up (Clark et al., 2011; Ferrier et al., 2011; Lewin et al., 2002; Zetta et al., 2011).

Such positive changes may not endure, however. In the OASIS trial, 65% of current smokers had quit at 30 days but only 25% of the quitters were still not smoking at 6 months (Chow et al., 2010). Recommended secondary prevention targets for blood pressure, waist circumference, cholesterol, or physical activity are not always achieved in the short-term, emphasizing the importance of secondary prevention initiatives (Murphy et al., 2011).

Psychosocial Risk

A recent meta-analysis has disaggregated the effects of the psychosocial element of CR (Whalley et al., 2011) and compared interventions combining psychosocial and exercise-based strategies with those based on psychosocial approaches alone. This revealed that psychosocial intervention, delivered by staff trained in psychological intervention, had only a modest effect on cardiac mortality, no reduction of risk in terms of total mortality, and no impact on revascularization rates or nonfatal infarction. This was in contrast to findings from an earlier systematic review (Welton et al., 2009), which included mixed intervention studies, for example, combining psychological intervention with exercise. Interventions based upon client-led discussion of cardiovascular risk and emotional support or including family members in the therapy were negatively associated with depression. Psychosocial intervention have little effect on HRQoL, perceived stress, Type A behavior, anger, and perceived exhaustion (Whalley et al., 2011). Psychological interventions targeting Type A behavior are most effective in treating or reducing depression.

Nonpharmacological interventions may improve symptoms of depression. For example, a 12-week depression care management program for hospitalized cardiac patients showed benefit at 6 and 12 months post-ACS event (Stafford et al., 2009). A shorter 6-week CBT program, demonstrated similar benefit in depressive symptoms (Hambridge et al., 2009); however, this brief intervention was delivered to an established, well-motivated group already taking part in CR and was delivered by skilled clinical psychologists (Hambridge et al., 2009) creating challenges in the transferability of this approach. Programs based on the principles of CBT can facilitate patient skills to manage depression and make positive lifestyle changes (Berkman et al., 2003).

Educational Intervention

Systematic reviews of CR have explored the effectiveness of the educational component of CR alone rather than as part of a CR program in combination with an exercise or psychological intervention (Brown et al., 2011). Patients/families receiving educational sessions in the form of instructional activity from a health care professional, ranging from 2 short periods of contact to a 4-week residential placement, were no different than those receiving standard care in terms of outcomes including cardiac and total mortality, revascularization, hospitalizations, and readmissions. Improvements in HRQoL and reductions in health care costs suggest that education is still a vital component of CR, but by itself there is little evidence of effect beyond these outcomes (Brown et al., 2011).

Exercise

The exercise component of CR has been compared to comprehensive CR (Heran et al., 2011). Exercise only CR is highly effective in reducing overall and cardiac mortality and reducing the number of hospital admissions. This form of CR does not reduce the risk of subsequent MI, coronary artery bypass grafting or *percutaneous transluminal coronary angioplasty*. Exercise-based CR led to an increase in HRQoL in 7/12 trials examined. This positive effect may result from a direct effect of exercise on physiological outcome, or may be mediated by improvement in the risk factors for atherosclerosis, e.g., reductions in lipids, smoking, and blood pressure. Home-based exercise, often based around increasing activities such as walking, is equally effective compared with center-based programs (Taylor et al., 2010).

Understanding and Improving Uptake and Adherence

Despite CR remaining the main stay of treatment following an acute coronary event, only 42% of those eligible actually take part (BACPR, 2012). Reasons for low participation are multifactorial. Four broad factors are associated with cardiac rehabilitation attendance. These include sociodemographic factors such as age (Artham et al., 2008), diagnosis (Turner et al., 2002), infrastructure-related issues such as transportation or referral (Glazer et al., 2002; Jackson et al., 2005), and psychological or cognitive variables associated with CR attendance and adherence including depression and anxiety (Whitmarsh et al., 2003).

While patients with elevated depression scores are as likely as nondepressed to enroll in CR (Farley et al., 2003), they are 2.2 times less likely to complete CR after controlling for age, gender, BMI, and employment status (Casey et al., 2008). Ongoing anxiety and depression can lead to reports of poorer health status (Pedersen et al., 2006) and reduced compliance with treatments, behavior, and lifestyle modification (Kronish et al., 2006).

Perceptions of high controllability, severity, and the significant consequence of ACS are particularly strong predictors of CR attendance (Taylor et al., 2011). Beliefs about the necessity of CR and concerns regarding CR are also predictive (Cooper et al., 2007). High self-efficacy has been strongly associated with cardiac rehabilitation attendance (Jackson et al., 2005). Patients receiving practical support were 3.6 times more likely to adhere to medication than those with no support and were more likely to attend CR (DiMatteo, 2004; Molloy et al., 2008). While national guidelines suggest that the involvement of a significant supporting other (e.g., friend, partner, or family member) is as important as the prescription of cardioprotective medication and behavioral and medical risk factor management (BACPR, 2012), a recent meta-analysis concluded that CR based on therapeutic approaches including families had little effect (Whalley et al., 2011).

An intervention based around the use of motivational letters using a theory of planned behavior approach improved attendance (Mosleh et al., 2009), while a liaison nurse improved attendance rates, this approach failed to deliver any reduction in cardiovascular risk factors (Davies et al., 2010b). Evidence of improved adherence to exercise within a CR program is limited. Increased adherence to unsupervised exercise has been demonstrated in patients already attending a structured CR (Duncan and Pozehl, 2002) but this may be limited to patients who are likely to attend and complete CR. A combination of action planning and coping resulted in greater exercise adherence than for patients exposed to coping, or action planning alone (Sniehotta et al., 2006).

Despite these impressive initial improvements attained while participating in CR, achieved benefits may not be maintained over time. Adherence to CR is critical since patients who do not engage or dropout prior to completion are at greater risk of experiencing further cardiac events than those who attend all recommended sessions (Taylor et al., 2011).

Conclusion

This article has presented considerable evidence of the effectiveness of CR as a psychosocial intervention. Not surprisingly, the greatest evidence of effect of CR is seen in combined comprehensive programs. Psychological risk factors, such as cardiac misconceptions, illness, and treatment representations are likely to affect uptake and adherence to CR (BACPR, 2012).

Despite this evidence of benefit, uptake, and adherence to CR remains relatively low. Attempts to understand patterns of attendance of CR are critical in building an evidence base to improve uptake and adherence. Current studies exploring these issues are often based on sound psychological models, and

attempt to measure dynamic psychosocial processes, but do so using retrospective methods of data collection prone to recall bias, and by the use of designs limited by two or three longitudinal data collection points. There is a need, therefore, for additional longitudinal studies with several data collection points to establish predictors of attendance at CR measuring motivation, mood, illness, and treatment beliefs (e.g., Herber et al., 2012). Only in this way will we understand changes in patterns of the predictors of noncompletion and nonattendance allowing the development of interventions to increase uptake and thereafter adherence.

Rehabilitation of the Offender

Friedrich Lösel, University of Cambridge, Cambridge, UK; and University of Erlangen-Nuremberg, Erlangen, Germany

Abstract

Programs of offender rehabilitation aim to reduce reoffending and promote a noncriminal lifestyle. In contrast to the 'nothing works' doctrine of the 1970s, research on 'what works' has shown a desirable mean effect of 10–20% less reoffending. Cognitive–behavioral programs, hierarchical therapeutic communities, multisystemic therapy, education, vocational training, and restorative justice measures are supported by evidence. Counseling, low-structured case work, mentoring, sports programs, electronic monitoring, and medication for specific offender groups are promising, but need more sound evaluations. Purely deterrent and punitive measures show no or even slightly negative effects. Programs that adhere to the Risk-Need-Responsivity Model reveal particularly positive outcomes. Currently, there is a trend to integrate findings from desistance research and other concepts. More attention should be paid to the many moderators of effectiveness such as characteristics of the program, institutional context, participants, and evaluation methods.

The reactions of societies to those who break criminal laws vary across cultures and times. Over the last century in many countries corporal punishment and death penalty have been replaced by fines, prison sentences, and alternative sanctions such as community service or social training courses. Incarceration rates differ substantially and are, for example, 10 times higher in the United States than it is in Scandinavia. Such figures are only loosely related to national crime rates but depend, among other reasons, on a different emphasis given to the penal aims of compensation of guilt, protection of the public, general or specific deterrence, retribution, and the topic of this article: rehabilitation.

In general the term 'rehabilitation' refers to the regeneration of a previous state. With regard to offenders it means a process of reintegration into society, although those who come from very deprived backgrounds may have never been well integrated before. Related terms are 'resocialization' and 'correctional treatment.' The latter does not imply that most offenders need to be cured of a mental health problem. The interventions may include psychotherapy or medical treatment as well as education, vocational training or supervision. In practice, rehabilitation refers to all measures and processes that aim to reduce reoffending. This aim may be achieved via pathways such as adequate accommodation, education and employment, mental and physical health, reduced alcohol and drug problems, solid financial resources, stable family relations, and noncriminal attitudes, thinking, and behavior (Home Office, 2004).

The idea of offender rehabilitation has already been emphasized in the eighteenth and nineteenth centuries by Cesare Beccaria and Franz von Liszt who pleaded for sanctions that enable offenders to desist from crime. During the 1960s and early 1970s there was not only great therapeutic optimism, but also critique from different political directions that advocated tough punishment, wanted to avoid the costs of rehabilitation, feared a forced personality change of offenders or aimed for 'just deserts' punishment. The therapeutic optimism came to a halt when Lipton et al. (1975) carried out a systematic review and Martinson's (1974) prepublication of this study led to the widely cited doctrine of 'nothing works' (for details see Cullen, 2013; Lösel et al., 1987; Palmer, 1992).

From 'Nothing Works' to 'what Works'

The main message of Lipton et al. (1975) was not a proof for 'nothing works,' but a lack of methodologically sound evaluations. Furthermore, the authors only counted significant versus nonsignificant results and did not calculate comparable effect sizes. In contrast, early quantitative meta-analyses of controlled studies showed significant desirable effects of correctional interventions (Andrews et al., 1990; Lipsey, 1992a; Lösel et al., 1987). Since then dozens of meta-analyses of hundreds of primary evaluations revealed mean positive effects of programs for general, violent, sexual, and other offender groups. Some meta-analyses are listed in **Table 1**.

The mean effects vary between *d*-coefficients of 0.20 ± 0.10. They are small but by no means trivial effects. If, for example, the recidivism rate in the control group is 55%, the respective rate in the treated group would be 45%, a reduction of 10% points or 18%. As the base rates in sexual recidivism are lower, the percentage reduction can be larger in studies of sex offender treatment.

Overall, the effects in offender treatment are smaller than in various other fields of psychosocial intervention (Lipsey and Wilson, 1993). This is insofar plausible as offender treatment is more or less coerced in nontherapeutic milieus, many offenders have accumulated problems (i.e., substance misuse, low education) and evaluations use official recidivism after several years as the main outcome criterion. Although the latter is a distal and not a very sensitive indicator of treatment impact (particularly in case of minor offences) it is most important for policy making.

Different Types of Program

Nearly all meta-analyses on offender rehabilitation have shown differences in effect size between types of programs (Lipsey and

Table 1 Average effects of various meta-analyses on offender treatment

	Number of studies	*Effect size (d)*
Programs for general (i.e., violent, acquisitive) offenders		
Andrews et al. (1990): Various program types (i/a)	154	0.20
Dowden and Andrews (1999): Programs for female offenders (i/a)	45	0.28
Landenberger and Lipsey (2005): Cognitive–behavioral programs (i/a)	58	0.24
Lipton et al. (2002a): Therapeutic communities and milieu therapy (i/a)	42	0.28
Lösel et al. (1987): Treatment in social–therapeutic prisons (i)	18	0.22
Petrosino (1997): Various program types, randomized studies (i/a)[a]	115	0.20
Redondo et al. (1999): Various program types in Europe (i/a)	32	0.24
Programs for juvenile offenders		
Gottschalk et al. (1987): Various types of programs (a)	101	0.12
Koehler et al. (2013b): Various program types in Europe (i/a)[b]	25	0.16
Latimer et al. (2003): Various program types (i/a)	176	0.18
Lipsey (1993): Various program types (i/a)	397	0.10
Lipsey and Wilson (1998): Various program types, serious and violent offenders (i/a)	200	0.12
Whitehead and Lab (1989): Various program types (i/a)	50	0.24
Programs for sexual offenders[c]		
Aos et al. (2001): Various program types (i/a)	14	0.19
Hall (1995): Various program types (i/a)	12	0.24
Hanson et al. (2002): Psychosocial interventions (i/a)	43	0.12
Lösel and Schmucker (2005): Psychosocial and biological interventions (i/a)	80	0.28
Hanson et al. (2009): Psychosocial interventions (i/a)	23	0.23
Schmucker and Lösel (2013): Psychosocial interventions (i/a)	28	0.20

Note: i: Institutional/custodial treatment, a: Ambulatory/community treatment, d: Cohen's *d*-coefficient, partially calculated from Phi coefficients or odds ratios.
[a]Effect without weighting for sample size, smaller effect when *n*-weighted (0.03).
[b]Including young adult offenders up to age 25 years.
[c]Recidivism for sexual offences only.

Cullen, 2007; Lösel, 2012a; MacKenzie, 2006). In the following, various treatment modes are briefly discussed.

Cognitive–Behavioral Treatment

Cognitive–behavioral treatment (CBT) has the broadest empirical support. Such programs are based on theories of social learning and contain sessions on self-reflection, anger management, self-control, social skills training, interpersonal problem solving, moral reasoning, and perspective taking/empathy (Andrews and Bonta, 2010; Hollin and Palmer, 2009; Lipsey et al., 2007). CBT programs are typically carried out in a group format and vary with regard to structure, content, intensity, and focus on cognitions versus behavior. They can reduce reoffending by approximately 10–30% and are suitable for general, violent, juvenile, sexual, drug-addicted, female, and other offenders. Modules on anger management, interpersonal problem solving, and cognitive skills training seem to be particularly important (Jolliffe and Farrington, 2009; Landenberger and Lipsey, 2005).

Therapeutic Communities, Milieu Therapy and Social-Therapeutic Prisons

Therapeutic communities (TCs) and milieu therapy are more comprehensive than CBT programs. TCs originally placed emphasis on democratic processes and self-governing, but many are now hierarchic and structured (Cullen et al., 1997). In custody, they contain a therapeutic social climate, relatively large numbers of therapeutic staff, intensive contact with the inmates, appropriate responsibilities, various modes of therapy, and a stepwise opening to the community. Social-therapeutic prisons in Germany incorporate elements of hierarchical TCs, but have similar organizational structures as in regular prisons (Lösel and Egg, 1997). TCs and milieu-oriented programs are appropriate for difficult groups such as personality-disordered, violent and drug-addicted offenders. Overall the mean effects are positive (Aos et al., 2001; Holloway et al., 2008; Lösel, 1995b; Lipton et al., 2002b), but smaller than those of successful CBTs.

Multisystemic Therapy and Family-Oriented Programs

Multisystemic therapy (MST) and related programs are intensive, short-term, family- and community-based interventions for juvenile offenders (Henggeler et al., 2009). MST works with not only young people and their families, but also with schools, peers, neighborhoods, communities, and health care services. The approach is structured and manual-based, but not standardized. It uses broader therapeutic principles: for example, focus on the juvenile's social context, strengths and not only deficits, present- and action-orientation, development of appropriate behavior, continuity in effort, ongoing evaluation, and accountability. The interventions depend on the respective case. Meta-analyses have shown substantial reductions in recidivism (Aos et al., 2001; Curtis et al., 2004; Schmucker and Lösel, 2013), although there are some nonsignificant findings and methodological problems (Littell, 2006).

Education and Vocational Programs

Many offenders have deficits in basic education, low vocational qualifications, and histories of unemployment. As stable integration in the labor market is important for desistance from crime (Farrall and Calverley, 2006; Laub and Sampson, 2007), basic education and vocational programs are important. However, there is not much controlled evaluation on this topic. Academic education and vocational training programs reduce recidivism (MacKenzie, 2006; Wilson et al., 2000), but the effect of prison work and noncustodial employment programs are not yet well proven (MacKenzie, 2006; Visher et al., 2006). Such measures may be successful only if there is a demand in the labor market and if the offenders acquire personal skills to retain a job. Therefore, a combination with psychosocial interventions seems to be important.

Low-Structured Therapy and Counseling

These measures are often based on psychodynamic and humanistic concepts or contain eclectic case work. They aim to realize basic therapeutic principles such as emotional acceptance, empathy, openness, mutual bonding, and support. Psychodynamic approaches use a more educative format than in the traditional 'talking cure.' Some meta-analyses did not support these types of programs (e.g., Andrews et al., 1990), but others showed more desirable effects (Lipsey and Wilson, 1998; Pearson et al., 2002; Redondo et al., 1999). The relatively small and mixed effects may partly be due to the heterogeneity and low structure that can reduce program integrity. However, the basic therapeutic philosophies are relevant in many interventions (Lipsey, 2009; Lösel and Egg, 1997).

Mentoring Programs

Counseling is also a part of mentoring programs. These involve a helping, nondeviant reference person who forms a relationship with a young offender, gives advice, and functions as a role model. Meta-analyses show small positive effects on aggression and delinquency (Tolan et al., 2008), but there is not yet sound evidence that mentoring reduces reoffending in the longer term (Jolliffe and Farrington, 2008). It seems to be most promising in the context of more comprehensive interventions and for young offenders with no protective social network.

Restorative Justice Programs

Restorative justice (RJ) aims for conflict resolution and reparation of the harm caused to victims and other stakeholders. The offenders should show insight into the harm they have done, truly regret, and be willing to take concrete steps to compensate (where appropriate). RJ programs range from victim-offender-mediation and conferencing to restitution and community services (Ahmed et al., 2001; Sherman and Strang, 2007). Evaluations of various British RJ schemes showed a reduction in the frequency of reoffending and a financial payoff, but no significant effect on offense seriousness (Shapland et al., 2008). International reviews suggest desirable effects on recidivism (Sherman and Strang, 2007), in particular for face-to-face conferences convened by professionals and involving offenders, victims, and other stakeholders. Offender–victim mediation is not equally meaningful for all offender groups, that is, personality disordered or drug-addicted offenders would need more intensive treatment. However, as successful RJ contains elements of CBT more integration of RJ and treatment could be worthwhile.

Sports and Adventure Programs

Sport may help (young) offenders to learn rules and discipline, strengthen achievement motivation, cooperate with others, become healthy, satisfy needs for thrill and action, engage in nondeviant behavior, and increase self-efficacy and self-worth. As a consequence, these experiences may contribute to rehabilitation. Although sport is popular among offenders, there is little well-controlled research on its effect on reoffending. Correlational studies on sports and delinquency showed no or even a risk relation, particularly for boxing and martial arts (Endresen and Olweus, 2005; Lösel and Bliesener, 2003). In contrast, evaluations of sports programs suggested a reduction in offending (e.g., Nichols, 2007), but most studies used pre–post-designs and not equivalent control groups. Systematic reviews of adventure, challenge, and wilderness programs for young offenders suggest a desirable effect (Wilson and Lipsey, 2000). More well-controlled evaluations are needed.

Biological Treatment

Neurobiological research on serious offenders has made substantial progress (Raine, 2013). In forensic hospitals medication plays a key role with regard to underlying mental illnesses such as depression or schizophrenia, but biological measures are also promising in other fields of offender treatment. Only a few examples can be mentioned here: Substitution programs for drug-addicted offenders worked in reducing recidivism (Koehler et al., 2013). There were also positive findings on anti-androgen treatment for subtypes of sexual offenders (Lösel and Schmucker, 2005). Selective serotonin reuptake inhibitors (SSRIs) showed desirable effects in personality-disordered clients (Bellino et al., 2011). In a large study of patients with Attention-Deficit Hyperactivity Disorder (ADHD) medication strongly reduced the risk of later criminality (Lichtenstein et al., 2012). In a randomized experiment, a diet that aimed for healthy brain functioning reduced antisocial behavior in prisoners (Gesch et al., 2002). More well-controlled and large-scale evaluations of biological interventions are needed, including data on potential negative side effects. Biological interventions would not imply that crime is no longer seen as a primarily social phenomenon, but more integration with psychosocial approaches would follow a model that is well-established in the treatment of depression.

Deterrence and Punishment

Most offender rehabilitation programs are embedded in the basically punitive context of criminal justice. Therefore, it is important whether punishment alone has a deterrent effect and reduces the offender's recidivism. Many people say 'yes,' however, already first-time imprisonment seems to have no deterrent but a slightly criminogenic effect (Durlauf and Nagin, 2011). Comprehensive research reviews revealed no difference or even somewhat higher reoffending rates in comparisons of custodial versus community sanctions or longer versus shorter imprisonment (Killias et al., 2006; Nagin, 2013; Smith et al., 2002). The findings on 'shock incarceration' or 'scared straight' programs are also negative (MacKenzie, 2006; Petrosino et al., 2003). Similarly, boot camps with tough military-like regimes showed a zero mean effect (Aos et al., 2001; MacKenzie, 2006). Only a combination with educational and treatment components may have a rehabilitative impact. Of course, as mentioned, rehabilitation is not the only aim of custody and a proportion of ex-inmates do not reoffend, for example, due to self-critical reflection or getting older. However, negative aspects of incarceration (Listwan et al., 2013) are not only relevant for 'pure punishment,' but

also for rehabilitation-oriented custody, for example, contamination effects, break-up of social relations, and stigmatization after release. Accordingly, treatment in the community seems to be more effective than in custody (Lipsey and Cullen, 2007; Schmucker and Lösel, 2013).

Intensive Supervision

Some reviews of intensive supervision, intermediate sanctions or 'smart punishment' in the community showed no or small positive effects in comparison to routine parole, probation, fines, or diversion (Aos et al., 2001, 2006; Pearson et al., 2002; Smith et al., 2002). However, criminogenic effects have also been recorded (Gendreau et al., 2000). Intensive community supervision only seems to reduce reoffending when accompanied by treatment or counseling (Aos et al., 2006). The potential of intensive supervision may be counteracted by an enhanced risk of failure due to the closer monitoring and, thus, more visible violation of licensing orders. The same applies to electronic monitoring that showed a mean zero effect in a meta-analysis (Aos et al., 2006). Although there are some promising results, more well-controlled outcome and process evaluations are needed (Renzema and Mayo-Wilson, 2005).

The RNR Model and Its Implementation in Practice

Based on the evidence from 'what works' the Risk-Need-Responsivity (RNR) model of Andrews et al. (1990) became particularly influential in practice. According to this concept appropriate treatment must match the offender's risk for reoffending (R), address his/her specific criminogenic needs (N), and use methods that fit to the individual's learning style (R). Meta-analyses showed that appropriate programs reduced reoffending by up to 60% (Andrews et al., 1990) or – more realistically – by approximately 20–30% (Andrews and Bonta, 2010). Treatment effects systematically increased with the number of principles realized (Andrews and Bonta, 2010; Hanson et al., 2009; Koehler et al., 2013b), whereas programs that met none of the three conditions even had a slightly negative effect.

The social learning theory background of the RNR model particularly supports CBT, but it is not limited to such programs. The model has been expanded by emphasizing organizational factors, staff skills, therapeutic relationships, offenders' strengths, and linkages to the community (Andrews and Bonta, 2010; Andrews et al., 2011; Lösel, 1995a). Such broader perspectives go beyond the content of single programs. In various countries they were transformed into accreditation criteria. For example, the Correctional Services Advisory and Accreditation Panel of England and Wales applies the following criteria:

1. clear model of change;
2. thorough selection of offenders;
3. targeting a range of dynamic risk factors;
4. effective learning and teaching methods;
5. skill-orientation;
6. adequate sequence and duration;
7. promotion of offender motivation;
8. continuity of services;
9. ensuring program integrity;
10. ongoing evaluation.

Within a decade many programs for various offender groups have been accredited. Measures of systematic offender assessment, staff training, supervision, and auditing (mainly in prisons) have been implemented to ensure quality. The National Offender Management Service (NOMS) has been established for more integration of prison and probation services. The fast roll-out of offending behavior programs inevitably led to some implementation problems and, in particular, to deficits in controlled evaluation (Maguire et al., 2010). Quasi-experimental studies showed some encouraging findings, but also mixed results (Harper and Chitty, 2005; Hollin, 2008). However, in a large study of more than 17 000 participants of the custodial Enhanced Thinking Skills program there was a reduction in reoffending by 12% in comparison to a national cohort of offenders matched for risk and sentence length (Travers et al., 2013b). The overall decrease in reoffending in England and Wales during the last decade (Ministry of Justice (2013)) may partially be attributed to the large-scale implementation of rehabilitation programs; however, this is only indirect and not robust evidence.

The Good Lives and Desistance Concepts

Not surprisingly, there are also critical discussions of the evidence-oriented 'what works' approach (Brayford et al., 2010; McNeill, 2006; Ward and Maruna, 2007). These authors note a one-sided focus on standardized CBT and RNR programs, a danger of reduced creativity in practice, too demanding procedures of accreditation and audit, and not enough attention to systems and institutional issues. Particularly influential arguments came from Ward and colleagues (Ward and Maruna, 2007). Although they acknowledged the evidence for 'what works,' they felt that such measures do not inform offenders about the rewards of desisting from crime, neglect the role of the offender's self-directed actions, ignore the individual's need for specific experiences, use a psychometric model, do not address the role of treatment alliances, and often contain a 'one-size fits all' approach (Ward and Brown, 2004). As an alternative, Ward proposed the Good Lives Model (GLM). This integrates ideas from positive psychology, humanistic therapy, social learning, and strain theory. It assumes that offenders – like all human beings – want to achieve legitimate goals. This requires competences and resources to reach basic goods, that is, healthy functioning, knowledge, excellence in work and play, autonomy and self-directedness, inner peace and freedom of stress, friendship and community, spirituality, happiness, and creativity. Rehabilitative approaches should be designed to help the offender reach such good goals.

Although the GLM is not explicitly related to resilience research it is in accordance with its empirical findings on protective factors (Lösel and Bender, 2003; Rutter, 2012).

However, the above arguments against the 'what works' approach contain some stereotypes of the broad range of evidence-oriented programs (Lösel, 2012a). Expansions of RNR have already addressed various critical issues (Andrews et al., 2011), although therapeutic relationships and individualization indeed require more attention. Instead of conceptual polarization it needs to be seen whether the GLM achieves a robust empirical basis.

Another important widening of the 'what works' perspective comes from research on criminal careers and desistance. In a 'desistance paradigm' (McNeill, 2006) the focus switches from individual-oriented programs to social institutions and protective factors in the offenders' natural development. For example, marriage to a nondeviant partner, stable employment, social support from a prosocial network, active coping processes, experiences of self-efficacy, realistic future planning, and other social and personal resources can contribute to turning points in life and desistance from crime (Farrall and Calverley, 2006; Laub and Sampson, 2007; Lösel and Farrington, 2012; Maruna, 2001; Theobald and Farrington, 2009). The focus on desistance is not in conflict with the 'what works' approach. Although more weight is given to community services (including probation), social resources and individual strengths, programs that aim for reducing reoffending can easily be seen as measures that may help to start or continue processes of desistance in the natural context (Lösel, 2012a; Porporino, 2010). Correctional treatment programs also remain important to cope with internal or external obstacles to desistance (Bottoms and Shapland, 2011) and help to leave a criminal pathway as early and as long as possible.

'What works' and desistance research should become more integrated to benefit from each other and improve correctional practice. For example, evaluations of treatment programs can apply sound (quasi-) experimental designs that provide stronger evidence for causal processes than the correlational designs on protective factors (Lösel and Farrington, 2012). When the latter are replicated they need to be targeted in rehabilitation programs. MST, TCs, or social therapy are examples in which this is already taken into account. Another example is the inclusion of motivational modules and cognitive interviewing in CBT and similar programs (McMurran, 2002). A third example is measures that can help to strengthen protective family bonds during resettlement (Lösel et al., 2012).

Multiple Influences in Offender Rehabilitation

The above discussion shows that the focus on isolated rehabilitation programs should be widened to broader characteristics of 'what works.' This is also suggested by substantial outcome variation of different implementations of the same or rather similar programs (Lipsey and Wilson, 1998; Schmucker and Lösel, 2013; Tong and Farrington, 2006). Nearly all meta-analyses show that the program content explains only a part of the variance in effect size and many other factors can have an impact. **Figure 1** contains a model that summarizes some potentially relevant factors.

Program Factors

Program Content

This type of program is relevant for its effectiveness, but most studies refer to the concept and not to its factual implementation (Lösel, 1995a; Shaffer and Pratt, 2009). Therefore, it is important to assess what was *de facto* implemented as part of the descriptive validity of evaluations (Lösel and Köferl, 1989). Better the documentation, larger the effects (Schmucker and Lösel, 2013).

Quality of Program Implementation

Even the best rehabilitation programs may show no effect when they are not properly delivered. Accordingly, effects are stronger when there is sound integrity in implementation (Andrews and Dowden, 2006; Lipsey et al., 2007). Careful staff selection, training and supervision are only some of the factors that enhance Integrity.

Program Intensity

The RNR model suggests that the intensity of an intervention should match the offenders' risk of recidivism. Accordingly, more intensive programs (longer duration, more sessions) tend to show better effects in groups at higher risk (Latimer et al., 2003; Lipsey et al., 2007).

Individualization

As mentioned above a fully standardized approach may not be optimal because one size does not fit all. Although there is a lack of research on this issue, some degree of individualization seems to provide better effects in sexual offenders (Schmucker and Lösel, 2103). The positive findings on MST point in the same direction.

Control Condition

The effects in evaluations also depend on the conditions in the untreated control groups (Lösel and Egg, 1997). As routine reactions in the criminal justice system have improved in many countries, this may lead to reduced effect sizes in more recent evaluations (Jolliffe and Farrington, 2009; Lösel and Schmucker, 2005; Tong and Farrington, 2006).

Context Factors

Custody versus Community

Various meta-analyses showed larger effects in ambulatory than in custodial treatment (Andrews and Bonta, 2010; Koehler et al., 2013b; Lipsey and Cullen, 2007; Schmucker and Lösel, 2013). This may partially be due to the negative influences of incarceration. However, basic difficulties of knowledge transfer from a closed institution to the community and resettlement problems also play a role. Therefore, measures to support the resettlement process are highly relevant (Maguire and Raynor, 2006; Taxman and Belenko, 2012).

Institutional Climate

A positive organizational climate can promote behavior in prisons. This is not only relevant for the amount of conflicts,

Figure 1 A model of potential influences on the effects of correctional treatment. From Lösel, F., 2012b. What works in correctional treatment and rehabilitation for young adults? In: Lösel, F., Bottoms, A.E., Farrington, D.P. (Eds.), Young Adult Offenders: Lost in Transition? Routledge, Milton Park, UK, pp. 74–112.

violence, or suicides (Cooke et al., 2008; Liebling, 2005), but may also influence the impact of treatment programs.

Staff Factors

Staff–client alliances are highly relevant in psychotherapy. Accordingly, correctional treatment is more effective when staff have good relations with the clients, adequate reinforcement practices, and social competences (Dowden and Andrews, 2004). Therefore, staff selection, training, and supervision are essential for effective rehabilitation (Gendreau et al., 1999).

Continuity of Care

Custodial programs are more effective when there is adequate care after release (Farrall and Calverley, 2006; Maguire and Raynor, 2006). Similarly, measures of vocational training, employment, and accommodation should be related to psychosocial interventions to improve their impact.

'Natural' Protective Factors

'Natural,' personal, and social resources are relevant for desistance from crime (Farrall and Calverley, 2006; Lösel and Farrington, 2012; Maruna, 2001). Such resources are targeted in MST and Functional Family Therapy; however they should also be addressed in more circumscribed structured programs.

Offender Factors

Risk Level

Treatment effects are larger in medium and high risk offenders than in low risk groups who do not need a program to desist (Andrews and Bonta, 2010; Koehler et al., 2013b; Lipsey, 2009; Lipsey and Wilson, 1998; Lösel and Schmucker, 2005). However, very high risk offenders such as psychopaths or professional criminals are less responsive to treatment so that an inverse U-shaped relation between risk level and effect size seems to be plausible (Lösel, 1996).

Personality Factors

Psychopathic offenders are particularly difficult to manage (Lösel, 1998; Salekin et al., 2010). Similarly, types of sexual offenders, for example, with or without a deviant sexual preference (paraphilia) or an antisocial personality disorder have to be taken into account. Personality factors and crime-related attitudes are also likely to play a role when prisoners with burglary or robbery index offences do not benefit from CBT (Travers et al., 2013a,b).

Treatment Motivation

The motivation to change is now seen as a dynamic process and not as dichotomous static characteristic (McMurran, 2002; Porporino, 2010). Therefore, the implementation of motivational interviewing (Miller and Rollnick, 2002) and other strategies to cope with temporary lapse and relapse are important to enhance treatment effectiveness. Accordingly, mandatory treatment does not seem to be more effective than is voluntary participation (Koehler et al., 2013b; Schmucker and Lösel, 2013).

Treatment Drop Out

Offenders who do not regularly terminate a program often have relatively high reoffending rates (Koehler et al., 2013b; Lipsey and Cullen, 2007; Travers et al., 2013a,b). In addition to personal problems this can be due to an inadequate selection process or difficulties in program implementation.

Age of Offenders

According to the age–crime curve young offenders have a higher base rate of reoffending. However, there is a lack of direct comparisons in the effects of treatment programs at different ages. Overall, there seems to be a tendency of larger effects in studies of young offenders (Lipsey and Cullen, 2007; Redondo et al., 2002).

Other Biographical Factors

Most research on offender rehabilitation has been carried out in males. Basic principles and effects are similar in female offenders (Andrews and Bonta, 2010; Dowden and Andrews, 1999; Landenberger and Lipsey, 2005), although sexual abuse and intimate relationships are more important for women's delinquency. Ethnic minorities in the United States seem to benefit from the same programs as others (Landenberger and Lipsey, 2005; Wilson et al., 2003). More research on such issues in other cultures is necessary.

Methodological Factors

Design Quality

Contrary to other fields of criminology, it is not yet clear whether randomized experiments on offender rehabilitation reveal smaller effects than do weaker studies (Jolliffe and Farrington, 2009; Koehler et al., 2013b; Lipsey and Cullen, 2007; Lipsey and Wilson, 1998; Schmucker and Lösel, 2013). As evaluation quality has various aspects (Lösel, 2007) other moderators may interfere.

Sample Size

Studies of larger samples often show larger effects than small scale evaluations (Koehler et al., 2013b; Lipsey et al., 2007; Lipsey and Wilson, 1998; Schmucker and Lösel, 2013). This can be due to a 'publication bias' that favors significant effects. However, smaller studies enable a better monitored implementation that can lead to stronger effects.

Demonstration Studies versus Routine Practice

There is a tendency of larger effects in demonstration or model projects than in evaluations of routine practice (Andrews and Bonta, 2010; Koehler et al., 2013b; Lipsey and Landenberger, 2006; Lipsey and Wilson, 1998; Lösel and Schmucker, 2005). Therefore, one has to distinguish between program 'efficacy' and 'effectiveness.' Better monitoring and more selectivity are some of the factors that may contribute to larger efficacy than effectiveness.

Researcher Involvement

Researcher involvement in the development or implementation of a program often goes along with a tendency of larger effects. (z.B. Lipsey and Landenberger, 2006; Lipsey and Wilson, 1998; Lösel and Schmucker, 2005). This may be due to better quality management, but there is also a risk of conflict of interest (Petrosino and Soydan, 2005). Therefore, independent evaluations are necessary.

Outcome Measures

Official recidivism as an outcome measure contains various problems (Maguire, 2012), but it is the key criterion for policy and practice. Some studies showed stronger treatment effects in more serious offences, frequency of reoffending, or self-reported crime (Ministry of Justice (2013); Lösel and Schmucker, 2005). Personality questionnaires also indicate larger effects, but due to social desirability and other influences these are only weakly related to reoffending (Lipsey, 1992b; McDougall et al., 2009).

Length of Follow-Up

Many Anglo-American studies use rather short follow-up periods of 1–2 years. However, there is a trend of smaller effects in evaluations with a longer follow up (Lösel, 1995a; Lösel and Schmucker, 2013). This may indicate a decrease in program impact as well as deficits in aftercare and stressors in the community.

Conclusions and Perspectives

The 'what works' approach in offender rehabilitation has made substantial progress. Carefully implemented evidence-based programs such as cognitive–behavioral treatment, structured therapeutic communities and social therapy, multisystemic therapy, basic education, vocational training, restorative justice, and other approaches can reduce reoffending, whereas pure deterrence and punishment seem to be not effective. However, there are many characteristics of program, context, participants, and evaluation methods that have an impact on effectiveness. This complexity should be taken more into account to strengthen the 'what

works' in research and practice (Lösel, 2012a). Inter alia, this requires the following:

- differentiation of the theoretical bases of rehabilitation programs;
- more controlled evaluations of daily routine (instead of demonstration projects);
- increased process evaluation on program implementation and quality assurance;
- more systems orientation instead of isolated single programs;
- analysis of interactions between specific programs and the institutional context;
- increased awareness of interpersonal relationships and therapeutic alliances;
- more differentiation and individualization (instead of 'one size fits all');
- integration of natural protective factors in treatment concepts;
- more attention to neurobiologial factors that contribute to criminal behavior;
- more frequent direct comparisons of measures in community versus custody;
- increased sensitivity to issues of cost–utility;
- more sensitivity to national and cultural differences;
- more integration of developmental prevention and offender treatment.

If such strategies are followed step by step one can expect that a future-oriented and effective rehabilitation policy will make further progress.

Reification: History of the Concept

Frederic Vandenberghe, Institute for Social and Political Studies, State University of Rio de Janeiro, Brazil

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The concept of reification (*Verdinglichung*) is a central category of critical social theory. In the Hegelian-Marxist tradition, from Marx via Lukács to the Frankfurt School, it is used to denounce the alienation and dehumanizing impact of social systems under capitalism. Occasionally, it is also used to criticize the hypostasis of concepts and the transformation of humans into things by naturalist approaches of the social.

Until fairly recently, reification was a central diagnostic concept of critical social theory and social philosophy. Due to its heavy metaphysical baggage and its grounding in an obsolescent philosophy of history, the theory of reification has lost much of its credibility and prestige. To explain, describe, and criticize various forms of dehumanization in modern capitalist societies, it is occasionally rediscovered, refurbished, and actualized by authors within the Marxist tradition of Left Hegelianism. Through a grand narrative of reification, systemic processes of commodification, exploitation, and domination that lead to a loss of community (anomie), meaning (disenchantment), and freedom (domination) are connected to a phenomenological description of the alienation of the modern self from itself, others, and the world. As a critical category, reification squarely ascribes the blame of alienation to the system. The denunciation of reification is paradoxical, however, to the extent that it presupposes that the object is really a subject, it denies what it affirms (that the world is inhuman) and affirms what it denies (namely that there still is a subject that can act and change the world).

Literally, *reification* (*Verdinglichung*) refers to the transformation of human properties, relations, processes, actions, concepts, etc. into things. As a technical term, the term reification emerged in the English language in the 1860s out of the contraction of the verb *facere* (to make) and the substantive *res* (thing), which can refer both to concrete and empirically observable things (*ens*) and to abstract indeterminate things (*aliquid*). As a synonym of 'thingification,' the inverse of personification, reification metaphorically refers to the transformation of human properties, relations, processes, actions, concepts, etc. into *res*, into things that act as pseudopersons, endowed with a life of their own. Depending on the grammatical subject of reification – who reifies what: is it the analyst who reifies the concepts or is it society that alienates the subjects? – the transformation of human properties, social relations, abstract concepts, etc. into things and types can operate both on a methodological and on a social level.

The concept is never a neutral one. Positive instances of reification (Gehlen, Latour, and Virno) are rather rare, though. Usually, the concept is used polemically to denounce the 'violence of abstractions,' either of conceptual abstractions (*Denkabstraktionen*) that suppress the reflexive embeddedness of concepts into their social context, treat social facts as things, and transform metasubjects into megasubjects, or of real abstractions (*Realabstraktionen*) that strip individuals of their autonomy and reduce them to cogs of an abstract social machinery.

As a normative–descriptive concept that denounces the dehumanizing impact of social systems, such as the market, the state, or the bureaucracy, reification shows a family resemblance with the Marxist concept of alienation and with the Weberian concept of formal rationalization. Although the dialectical idea of objectivation (*Entäusserung*)–alienation (*Entfremdung*)–reappropriation (*Aneignung*) is already present in Hegel, the real history of the concept really begins with Marx and with Georg Lukács's Hegelian interpretation of Marx in "Reification and the Consciousness of the Proletariat," the central chapter of *History and Class Consciousness* (1923). In Marx, the concept is used in the context of the critique of the fetishism of commodities, to denounce the transformation of social relations into things. In his classic formulation of the theory of reification, which constitutes the paradigmatic 'hard core' (Brunkhorst, 1983) of the critical theory of the Frankfurt School, Lukács generalized Marx's concept of commodity fetishism, and fused it with Max Weber's concept of formal rationalization and Georg Simmel's concept of the tragedy of culture. Replacing the Marxist theory of class-consciousness with a Freudian theory of repression, the members of the Frankfurt School – Max Horkheimer, Herbert Marcuse, and especially Theodor W. Adorno – radicalized, universalized, and totalized the Lukács's theory of reification. Criticizing the Frankfurt School's identification of rationalization and reification, Jürgen Habermas reformulated the theory of reification in his theory of communication in terms of the colonization of the life-world by the subsystems of the economy and the administration of the state. Axel Honneth has also revisited the theory of reification and, inspired by the phenomenology of Sartre, he has reformulated it in terms of a theory of nonrecognition that foregrounds the lack of an existential relation between self and other. Although reification has received the greatest attention in Western Marxism, and above all in Lukács, it is important not to restrict the use of the concept to that tradition but to see that the concept and the word can also and already be found in the work of Kant, Hegel, Nietzsche, Dilthey, Husserl, Heidegger, Simmel, and Max Weber to criticize the dehumanizing, rationalizing, and alienating tendencies of modernity.

Methodological Reification – or the Critique of Conceptual Abstractions

In the philosophy of the social sciences, the concept of reification is used to denounce (1) the hypostasis of

concepts (nominalist critique of realism), (2) the naturalization of the subject and the life-world (humanist critique of naturalism), and (3) the ideological justification of the status quo (dialectical critique of fetishism).

Nominalist Critique of Realism

In the case of the critique of naive conceptual realism (or reism), the notion of reification of concepts is used to denounce, from a nominalist, vitalist, or criticist perspective, the categorical error of transforming abstractions (notions, representations, and concepts) into a material reality, in a concrete object 'out there.' Reification is here understood as a synonym of the hypostasis of concepts, analytical constructs, and ideal types. It occurs when one slides 'from the substantive to the substance' and identifies the categorical thing with the 'thing in itself.' This is, for instance, the case when scientific concepts (e.g., general intelligence, the social system, and modernity) are identified with concrete, empirical entities or when macrosociologists transform their own conceptual constructs or those of the actors ('the State,' 'the Bourgeoisie,' 'the Proletariat') into historical subjects capable of agency and of determining their own ends ('the State decides,' 'the Anglican Church resists,' 'the glorious Proletariat triumphs,' etc.). It should, however, be noted that due to the absence of a consensus on the ultimate referents of reality and the fact that one can always submit the concepts of the scientist to a neo-Kantian critique of ontology, the charge of reification is almost inevitable. Given that one's typification is another's reification, the critique of the 'fallacy of misplaced concreteness' (Whitehead, 1926) is endemic in sociology.

Humanist Critique of Naturalism

The critique of positivist naturalism in terms of reification of the subject is linked to the series of methodological disputes (*Methodenstreit*) which, since the double foundation of sociology by Comte and Dilthey in the nineteenth century, have opposed the partisans of the method of causal explanation (*Erklären*) to the partisans of the interpretative methods (*Verstehen*). Drawing on Vico's principle of the *verum factum (verum et factum convertuntur)* – according to which we can understand the sociohistorical reality because it is a human product, but not nature which is a divine product – humanists claim that the appropriate method of sociology is interpretative in that it aims to understand – by means of a phenomenological and hermeneutic reconstitution of the meaning of action – the social-historical world (Hegel's objective spirit) as an objectivation of subjective actions. Social facts thus have a meaning and cannot be treated 'as if they were things' (Durkheim). The naturalistic elimination of the meaningfulness of action through statistical observation is reifying, in that it transforms psychic acts into pseudophysical facts and reduces culture to (second) nature. Against Durkheim and his fellow 'factists' who 'change the subject' of the human sciences by substituting factors for actors, humanists thus argue that social facts are not things but that things are social facts whose meaning can be understood and which can be interpreted as an 'ongoing accomplishment of the concerted activities of daily life' (Garfinkel, 1967: p. vii).

Dialectical Critique of Fetishism

The dialectical critique of fetishism offers a metatheoretical critique of the ideological implications of *bourgeois* theories and methodologies of the social that – due to a lack of reflexivity on their context of genesis and application – legitimize the status quo. Dialecticians accept the limits of 'hermeneutic idealism.' When social relations have crystallized into a 'second nature' and social subsystems follow their own pseudonatural laws, 'dehumanizing' theories (e.g., structuralism, functionalism, and systems theory) and methods (e.g., linear modeling and statistical regression) can and have to be applied. But if one does not want to fall prey to a 'reification of the second order' and give a 'reified perception of the reifying' (Adorno) that willy-nilly endorses the reality it registers, the observed facts have to be 'mediated by the totality' (Lukács) and defetishized in such a way that the tension between the real and the possible, between what is and what could or should be, becomes perceptible within the facts themselves.

Social Reification – or the Critique of Real Abstractions

In German social philosophy and critical social theory, the concept is generally used to diagnose, i.e., describe and denounce, the pathological autonomization of social structures, systems, and subsystems – which, although man-made, are out of control – follow their own laws and alienate the actors, dominating them as if they were natural forces.

In the tradition of Western Marxism, Marx's theories of alienation and the fetishism of commodities are combined with Hegel's dialectical phenomenology of spirit, Georg Simmel's theory of the tragedy of culture, and Max Weber's theory of formal rationalization to form a critical theory of society. The concept of reification is used to refer to the relatively autonomous, alienating, and alienated functioning of the social and cultural (sub-) systems of modern capitalist societies that impose their constraints on individuals, limit their freedom, and tend to reduce them to powerless 'carriers' or passive 'executioners' of the system. As products of praxis, institutions and organizations are human objectivations, but in the course of their development, the cultural and social (sub)systems have been complexified, formalized, rationalized, and depersonalized to such an extent that eventually they have been transmuted into self-referentially closed systems that function independently of the will and the consciousness of individuals, thwart their plans, threaten their autonomy, and perhaps even their existence. The critique of reification is dialectical and thus somewhat paradoxical: the insistence on the alienating autonomy of the system aims to reactivate the autonomy of the individuals and to overcome their alienation.

Although the concept of reification (*Verdinglichung*) can already be found in Hegel's *Philosophy of Right*, the real history of the concept begins with Karl Marx and with Georg Lukács's Hegelian interpretation of Marx. The origins of the theory of reification are usually found just where the word itself is absent, namely, in the famous section on the fetishism of commodities (Chap. 1, Sect. 4) of *Das Kapital*. Analyzing

capitalism as a system of generalized exchange, Marx notes that the commodity has become the universal form of the product of labor, with the result that the exchange value of the commodity supplants the use value. Consequently, the exchange value appears to those who exchange goods as a property of the commodity itself, whereas in reality, it is the result of the labor that is incorporated in the commodity and that expresses itself as a quantitative relationship between the exchanged goods. "It is nothing but the definite social relation between men themselves which assumes here, for them, the phantasmagoric form of a relation between things" (Marx, 1869: p. 86). This inversion of humans and things is not simply an illusion, however, but an expression of the real nature of social relations in a competitive market environment. In the absence of a central organism that regulates both the production and the distribution of the products of labor, the social integration of humans is imposed from without by the systemic interconnection of things.

In "Reification and the Consciousness of the Proletariat," the central chapter of *History and Class Consciousness*, Lukács, a Hegelian-Marxist who was once a student of Simmel and Weber, presents the classic formulation of the theory of reification. Synthesizing Weber's theory of formal rationalization with Marx's theory of commodity fetishism, Lukács generalizes the theory of commodity fetishism beyond the sphere of circulation. In the problem of fetishism, which he immediately identifies with the phenomenon of reification, he discovers the "central, structural problem of capitalist societies in all its aspects" (Lukács, 1923/1968: p. 257). The universality of the commodity form, conceived as the prototype of all the forms of objectivity that follow their own laws and dissimulate the traces of human relations that subtend them, affects the life of everybody, both in its objective and subjective manifestations. Objectively, individuals are confronted with a second nature of pseudothings against which they are powerless; subjectively, they are estranged from their own activity, apprehending the products of their own activity in an alienated mode – 'as if they were something else than human products' (Berger and Luckmann, 1966). Moving from the sphere of circulation to the sphere of production, Lukács rediscovers the theory of the alienation of labor which the young Marx had developed but not published in the *Parisian Manuscripts* of 1844 (see Alienation, Sociology of). In the sphere of material production, reification expresses itself most clearly in the reduction of labor power to a commodity and of the laborer to an appendix of the machine. In capitalism, reification is generalized and the fate of the worker becomes paradigmatic of the fate of everyone. Expressing the messianism of the oppressed, Lukács eventually reintroduces the Proletariat as the 'identical subject–object' of history, whose revolutionary actions overcome alienation and reification, and thus realizes the Hegelian dream of the restoration of the 'beautiful totality.'

The development of the so-called Critical Theory of the Frankfurt School can best be understood as the result of a progressive disillusion with revolutionary expectations. Eliminating the Hegelian-Marxist dialectic of consciousness, which they replace by a Freudian account of sublimation and repression, Horkheimer, Marcuse, and especially Adorno, who also gave a Nietzschean twist to the concept of reification, radicalize the Weberian-Marxist strand in Lukács' theory. Universalizing and totalizing reification to the point that it appears as an ontological feature of human civilization, they almost end up indicting Reason as such. Indeed, to explain totalitarianism (in its fascist, communist, and capitalist variants), Horkheimer and Adorno develop a negative philosophy of history which uncovers, in the first protohistorical attempts to dominate nature, the origin of the fatal unfolding of a diabolic logic of increasing reification that will find its culmination (but not its endpoint) in the death camps. In his *Theory of Communicative Action*, Jürgen Habermas (1981), the main representative of the second generation of critical theory, reformulates the theory of reification in terms of the paradigm of language. In this perspective, reification is no longer associated with rationalization as such, as was the case with Max Weber and the Frankfurt School, but reconceptualized in terms of the 'colonization of the life-world' by the subsystems of the economy and the administration of the state. When the mechanisms of systemic integration (money and power) force back the forms of social integration from those domains that can only be integrated through language, a reification ensues that leads to a pathological deformation of the life-world. In a short essay on reification, Axel Honneth, the-main representative of the third generation of the Frankfurt School, has taken a new look at an old idea. By means of a linkage between his theory of recognition and a phenomenological theory of alienation, he disconnects the concept from its Lukácsian origins and predominantly conceives of it as a deficient relation to self and others. Understood as a pathological form of life in which participative forms of knowledge (recognition, reciprocity, and care) are systematically replaced and repressed by instrumental, representative, and manipulative approaches of the world, the other, and the self, reification is redefined in terms of forgetting of primordial way of being in the world.

Reinforcement, Principle of

Ian M Evans, Massey University, Wellington, New Zealand

Abstract

The principle of reinforcement is central to many psychological interventions designed to change behavior. All behaviors are influenced by their consequences, and when these are positive for the individual in some way, the response that preceded them is strengthened, that is, will be more probable when the antecedent conditions reoccur. Positive reinforcements are intrinsically valued, similar to rewards. Negative reinforcement occurs when aversive experiences, including distressing emotions, are reduced by some action, which is then strengthened. While not necessary for learning to occur, material and social rewards provide feedback essential for the shaping and maintenance of new behavior.

Reinforcement refers to two slightly different phenomena depending on the type of learning involved. In instrumental (operant) conditioning it is the presentation of any (usually desirable) event or object following a response, which results in an increased likelihood of that response reoccurring. In classical (Pavlovian) conditioning, reinforcement refers to the presentation of the stimulus that elicits the reflexive response (unconditioned response) that comes to be elicited by a new, previously neutral stimulus. With its evolutionary overtones (behaviors should be repeated or become more probable when they enhance the organism's adaptation or survival prospects), it is one of the most fundamental principles of learning. It is also the cornerstone of many practical interventions (psychological treatments) designed to change behavior, including skill development. Thus, the principle of reinforcement has wide application in clinical, educational, organizational, and community contexts. Recognition that many behaviors are determined by their consequences is a fundamental tenet of behavior therapy (*see* Behavior Therapy: Psychiatric Aspects), as well as for understanding psychological disorders.

The term 'reinforcement' can denote (1) a principle of learning; (2) a procedure designed to modify the frequency of an approved behavior; or (3) the consequence itself (also 'a reinforcer'). The term connotes 'strengthening,' and what is strengthened is the likelihood of a behavior reoccurring in a specific context. A stimulus is judged to be a positive reinforcement to the extent that it actually increases the likelihood of the behavior that preceded it. Thus, a reinforcement is not quite the same as a reward, since what constitutes reinforcement is defined in terms of what 'works' to regulate behavior, whereas a reward is identified by what an individual expresses a desire for, values, or will work to obtain. In practical applications, however, one selects reinforcements on the basis of prior experience, observation, and intuition that the planned consequence will be desired.

When the consequence (food, praise, stimulation, or even apparently negative outcomes such as experiencing pain, or annoying someone else) results in the behavior being more probable (likely to be repeated), it is referred to as positive reinforcement. When an organism works actively to eliminate unpleasant events currently in existence (such as being cold, teacher demandingness, loneliness, boring activities), it is known as negative reinforcement. When a consequence results in a behavior being less probable in the future it is known as punishment. Any previously neutral stimulus that signals the future likelihood of reinforcement comes to have reinforcing properties of its own, and is described as a secondary (or conditioned) reinforcement. Socially, money is the classic example. In applied contexts, a stimulus that has no value other than a designated rate of exchange with something else that is desired is called a token reinforcement – sometimes these are symbols such as poker chips, stars on a chart, or points that can later be exchanged for treats and privileges.

History of the Concept

Reinforcement's origin as a formal principle of modern psychology derives from Thorndike's (1927) Law of Effect: the occurrence of a 'satisfying' event strengthens the association between the setting and the behavior that was instrumental in producing it. Hull's (1943) influential learning theory also proposed that what is strengthened is the association between a prior stimulus (cue or context) and the response, with the mechanism underlying the reinforcement effect being the reduction in a basic biological drive, such as hunger or thirst. However, many stimuli can serve intrinsically as reinforcement when they have only incentive value (such as a sweet but nonnutritive substance). Intrinsic reinforcement can also be thought of as satisfying secondary, social needs, for example, security, acceptance by others, entertainment, or feedback that your response was correct in some way – the latter being the intrinsic reinforcement in many electronic games and puzzles.

The amount, frequency, and quality of the reward influences its reinforcing function, but not in exactly the same way across different animal species. Much past research has been devoted to the question of whether reinforcement is necessary for learning to occur – many early theorists suggesting that 'latent' learning takes place when no reinforcement is present, although the evidence for this is ambiguous (for a discussion, see Jensen, 2006). The question, however, may be a spurious one, since it is difficult to imagine a behavior that has no consequences, and the positive nature of the outcome might be as simple as reducing constraints on the individual, or predicting future pleasures.

In the classical conditioning paradigm (*see* Classical Conditioning Methods in Psychotherapy; Clinical Psychology in Europe, History of; Clinical Psychology in North America, History of), Pavlov also used the term to refer to the unconditioned stimulus (UCS): the stimulus that evokes the

reflexive response. When this stimulus is regularly paired with and thus predicted by a neutral stimulus, the latter comes to evoke a somewhat similar response. The UCS is thus considered reinforcement, since its occurrence increases the tendency to emit a response in the presence of a previously neutral stimulus. Of considerable theoretical and practical importance is the phenomenon that when the UCS is removed and the previously neutral stimulus presented repeatedly, the conditioned response eventually ceases to occur. This phenomenon, as well as the procedure of removing the UCS, is known as extinction. It has an exact parallel in instrumental (operant) conditioning: if the activity no longer produces the positive outcome, its probability decreases.

Although central to both conventional instrumental and classical learning situations, the concept of reinforcement has acquired much of its practical, applied implication from Skinner's (1969) instrumental conditioning paradigm known as operant conditioning. The typical laboratory procedure is for a specific 'operant' response, such as depressing a lever or pushing a button, to result in the automatic delivery of a small amount of food for a hungry animal. The operants studied have been discrete, simple responses that can be repeated easily by the subject. A vast body of experimental research has demonstrated that the form, intensity, and temporal pattern (rate) of responding is a function of the rule specifying the relationship between the operant response, its consequence, and the context in which the consequence occurs (referred to as the 'three-term contingency'). In applied work, the analysis of these three components is often referred to as an A-B-C analysis: specifying the antecedents (situation, context, or triggering stimulus), the behavior, and its consequences.

Contingency Principles

The effectiveness of this procedure for developing or maintaining a specified behavior is influenced by the immediacy and predictability with which the reinforcement is delivered. Although it will slow the initial acquisition of new responses, the reinforcement need not be delivered after every response, an arrangement called a 'partial schedule of reinforcement.' The most common are ratio schedules, in which reinforcement is delivered after a specified number of responses, and interval schedules, in which reinforcement is delivered to the first response occurring after a predetermined period of time has elapsed. In the laboratory, these different schedules of reinforcement produce characteristic patterns of response rate. Analogies are often made with workplace contingencies; for example, if one is paid on a piecework basis it is a ratio schedule, whereas being paid every month is an interval schedule of reinforcement. Reinforcement can also be delivered intermittently, that is to say after a randomly variable number of responses or periods of time – gambling on a slot machine is an example.

Of importance for application is that intermittent reinforcement results in a behavior being more resistant to extinction, meaning that the organism will persist in the behavior for longer periods of time even when the reinforcement has been withdrawn (extinction). In clinical situations, one might think that a behavior is maladaptive when it is apparently not being reinforced and should therefore extinguish. If the individual's history of reinforcement were known, however, it might be recognized that this behavior has been reinforced intermittently in the past.

The specific form of any behavior can be determined by differential reinforcement, in which the criteria for precisely what response will result in reinforcement are carefully specified. By changing or narrowing these criteria gradually, a behavior can be 'shaped' into a particular configuration. Similarly, it is quite common in practice to reinforce differentially, decreases in an undesirable behavior, or to reinforce only an alternative, more appropriate, behavior. Reinforcement is most effective in shaping behavior when it follows the response immediately. Thus, there is also considerable overlap in practice between the concept of reinforcement and that of feedback – providing people with information regarding the quality of their performance. Feedback can, however, impair performance by directing attention to self rather than the task at hand. Similarly, reinforcements elicit responses often incompatible with the response being reinforced – for instance, when given a pellet of food, the hungry animal stops what it is doing (lever pressing) and consumes the food. As a practical example, praising a child for playing quietly (social reinforcement) may disrupt that activity and elicit approach to the parent delivering the praise, the exact opposite of what the parent hoped to achieve.

Reduction in aversive or unpleasant conditions can strongly reinforce any behavior that results in such reductions. As many negative emotions, such as fear, shame, and jealousy, are highly aversive to most people, behavior (including passive behavior such as avoidance), which reduces these negative internal states will be reinforced. This phenomenon is often used to explain human behavior that seems maladaptive but which serves the function of reducing negative feelings, such as using drugs to reduce anxiety, escaping from threatening situations, or forming inappropriate romantic relationships to reduce loneliness.

Constraints in Generalizing from the Animal Laboratory

Despite the substantial body of knowledge derived from studies of animal behavior, the analogy between the operant laboratory and real life has limitations, as can be seen from the practical examples already given. Even for animals, laboratory contingencies are contrived – unlike foraging in the wild, there is no intrinsic relationship between a lever press and obtaining food. Behaviors that are typical of the species are more easily established by reinforcement than others that are not (Breland and Breland, 1961). There are some artificial contingencies operating in everyday life too, particularly work settings, in which a person is reinforced with money, food, or favors for activities desired by those controlling these reinforcements. But more commonly our activities are intrinsically and socially rewarding, for instance, reading a book is reinforced by enjoyment of the story as well as by teacher approval, or climbing a mountain may be reinforced by a sense of accomplishment in addition to the admiration of friends. It has long been debated that if an activity which is usually

reinforced intrinsically is placed under an artificial external contingency (such as a monetary payment), will this later interfere with the intrinsic reward, such that once the artificial reward is withdrawn, the frequency of the behavior will drop below its previous rate? While early research suggested this phenomenon might occur, resulting in some authors claiming that rewards can be detrimental (Kohn, 1993), a meta-analysis of the literature established that reinforcement does not harm an individual's intrinsic motivation (Cameron and Pierce, 1994).

Another major difference between reinforcement studied in the laboratory and the principles affecting human social behavior is that the verbal specification of a contingency can function much like an actual contingency. Thus, for example, people can be promised a reward for an activity and this will change their behavior, particularly if compliance with commands and directives has been reinforced in the past. Skinner referred to this as "rule-governed behavior" whereas more cognitively oriented theorists prefer to talk of expectancies. Bandura (1977), for example, argued that performance on a task depends partly on the expectation that a certain reward will be forthcoming (outcome expectancy). Another way an individual can learn about a potential contingency between a behavior and its consequences is to observe someone else being reinforced for an activity; this is known as vicarious reinforcement.

Most general behavior theories argue that there is a strong link between reinforcement and emotion. For example, Staats' (1996) A-R-D model proposes that stimuli serving as reinforcements (R) have simultaneous attitudinal (A) value (can elicit emotion) and discriminative stimulus (D) functions (can serve as a cue for approach). When environmental conditions deprive an organism of the opportunity to perform a behavior that would likely occur in a free choice situation, it will perform other activities in order to gain access to that behavior, a phenomenon referred to as the Premack (1965) principle.

Where reinforcement is artificial, such as a socially determined prize for a job well done, humans learn from prior experience the standard of performance that deserves to be rewarded. Even young children are unlikely to appreciate a reward given for performance that is below their own standard. Thus, although self-reinforcement is often included as a treatment component for enhancing self-control, it is unlikely to be influential over and above the intrinsic satisfaction of accomplishing one's own goals. Furthermore, if the outcomes achieved after much effortful behavior are less positive than expected, people tend to reevaluate the outcome in an upward direction, an effect known as cognitive dissonance (Lawrence and Festinger, 1962).

Motivation, Reward, and Individual Differences

Although the principle of reinforcement is strictly related to the contingency between a behavior and its consequences, much recent research has focused on the properties of events that are clearly identifiable as rewards, that is, the kinds of reinforcements individuals strive to obtain. Generally, rewards satisfy biological or social needs, but can also be thought of as providing pleasure (Berridge and Kringelbach, 2013). It is now known that active approach behavior and reward systems ('pleasure centers' in the brain) are linked in terms of neural processes and pathways. The earlier idea that biological needs such as hunger and thirst motivate behavior and reinforcement is that which reduces these drives has given way to more hedonic models in which reward elicits motivation and the pursuit of goals. Neural processes involving the mesocorticolimbic dopamine system are increasingly understood within neuroscience, and provide clues to such phenomena as the special nature of addiction; however these insights are beyond the scope of this article (see, e.g., Schultz et al., 1997). Thus, there are plausible biological mechanisms for personality differences in the degree to which a given individual is responsive to positive outcomes (Corr and McNaughton, 2008).

When individuals are particularly sensitive to reward ('reward dominant') it means that they are much more likely to be influenced by positive reinforcement contingencies than by punishment, and will judge not receiving a deserved reward more unfair than being punished for something they did not do. Relative sensitivity to reward over punishment may also be a characteristic of individuals exhibiting certain clinical syndromes, such as Attention Deficit Hyperactivity Disorder, conduct disorder, and recent onset schizophrenia. There are also individual differences in preference for a small but immediate reward as opposed to a larger but more delayed one – a pattern that is generally considered to be maladaptive and detrimental to individual success. Humans are more influenced by rewards they have chosen than those arbitrarily selected by someone else.

Reinforcement as Behavioral Regulation

Much current research in the operant tradition is concerned with predicting the effects of contingencies on the distribution of available activities. Neobehavioral theories that relate reinforcement to motivation (e.g., need reduction) have given way to economic-type theories that consider the sum total of potential behaviors in a situation as well as the sum total of reinforcements. One of the most important observations emanating from this approach is that if there is more than one operant being reinforced (a concurrent schedule), animals will distribute their responses more or less in proportion to the amount of reinforcement available to each one. This is known as Herrnstein's matching law (see Noll, 1995 for a discussion of its implications).

In answer to the apparent anomalies discussed in Section Constraints in Generalizing from the Animal Laboratory, contemporary reinforcement theory stresses homeostatic principles, referring to how an organism must adjust its actions to meet the demands of the environment. An organism will normally distribute its activities so as to minimize the demands (e.g., effortfulness of the response) and maximize opportunities, and this optimum – when there is unconstrained choice – is known as the behavioral 'bliss point' (Kessler, 2009). Once reinforcement is seen in this light, it gives credence to applied approaches in which there is an emphasis on enhancing choices and opportunities for

individuals in otherwise deprived environments, or those with limited responses in their repertoire.

Theories emphasizing behavioral regulation propose that contingencies serve to constrain the organism's free flow of behavior. Given the wide range of behavioral choices available to individuals in natural situations, it is logical that removing reinforcement for one behavior will not be successful in reducing this behavior unless another, more socially desirable behavior, can be reinforced. Clinical research has repeatedly demonstrated the value of reinforcing more appropriate alternatives. Since a systems model emphasizes that increases in one behavior must inevitably be accompanied by decreases in others, extinguishing undesirable behavior and reinforcing appropriate responses may be two sides of the same coin (Evans, 2013).

Conclusions

While context/behavior/outcome (the three-term) contingencies are essential elements in the shaping and development of new skills, the reinforcing event itself has complex influences on human behavior and often serves as a cue initiating other activities. The effects of reinforcement are relative – related to the levels of reinforcement for other possible behaviors – which has important implications for designing environments that will support socially desirable activities. That there are motivational and emotional properties of reinforcement should not be underestimated, such as experiencing success, the relief of reduction in anxiety, or the satisfaction of a craving. There are also cognitive properties, with the history of availability being judged by the individual and influencing expectancies regarding the relative outcomes of different actions. Past experience with certain types of contingencies and deprivation experiences influence the way an individual will respond to a given reinforcement. The relatively simple idea that all behavior has a function – achieves some outcome for an organism – and that function regulates or controls the behavior, is a critical insight for analyzing any behavior that one wishes to change. However, the reverse of this principle – that we can artificially manipulate behavior by managing its consequences – has proved more complex than it appears, partly perhaps because humans at least, resist the experience that they are being deliberately controlled.

Abstract

Successful goal-directed actions are strengthened and controlled by their favorable outcomes or positive stimulus consequences. This process, obviously critical for survival, is termed 'behavioral reinforcement.' Evidence reviewed here suggests that this important process is mediated by specialized dopamine, norepinephrine, opioid peptide, and cannabinoid brain systems, which produce behavioral reinforcement primarily by modification of individual neuronal firing rates rather than by rearrangement of cellular circuitries.

Introduction

The brain's reinforcement systems, when activated by natural rewards or cues that predict rewards, necessarily release their reinforcing transmitters unselectively at all target sites. How then do these systems discriminate between correct and irrelevant responses to selectively strengthen only correct responses? It is convenient to assume that the unit of reinforcement is the target neuron itself, and not, as commonly believed, the complex circuits thought to underlie "whole" responses. A key idea is that, although all target cells receive chemical reinforcement messages indiscriminately, only recently-active target cells are eligible to be modified by them. Since correct responses always precede activations of the reward system, while irrelevant behaviors do not, only those target neurons whose activity mediates correct responses will be consistently reinforced. Finally, a molecular hypothesis of cellular reinforcement is described, which presents these ideas at a biochemical level.

Three Modes of Behavioral Control – Reflex Operant, and Habit

According to Skinner (1953), behavior is that part of the functioning of an organism which engages with or acts upon the environment. Although behavior is continuous, it is often convenient to regard the organism's activity as a succession of relatively discrete responses embedded in a stream of environmental stimuli. These stimuli may act in fundamentally different ways to control responses, depending on whether the controlling stimuli precede or follow the response.

In reflexes, the important controlling stimuli precede the response and elicit it. Some reflexes are inborn (unconditioned) and others are acquired through learning (conditioned). In unconditioned reflexes, the eliciting stimulus is innately effective (e.g., food in the mouth automatically elicits salivation). In conditioned reflexes, on the other hand, an originally ineffective stimulus becomes effective through a process of associative learning or stimulus substitution. For example, after several paired presentations of a bell and food, salivation comes to be elicited by presentation of the originally ineffective bell alone. Although unconditioned and conditioned reflexes may differ in certain ways, they share the same defining property. In all reflexes, conditioned and unconditioned, the direction of information flow in the brain is conventional – afferent (sensory) to efferent (motor).

Conversely – in a second mode of regulation termed 'operant conditioning' by Skinner – the critical stimulus follows the response and may increase or decrease its subsequent probability. Such stimuli are commonly called rewards or punishments, respectively, and the resulting behavior is variously described as reinforced, goal-directed, instrumental, or operant. Unlike reflexes, operant behaviors seem to require an unconventional neuronal circuitry in which efferents (response elements) are activated before afferents (reward-detecting sensory elements). But the brain mechanisms for operant conditioning do not require circuits that link efferent to afferent substrates. This is because operant-response neurons do not directly activate reward-detecting sensory neurons. Rather, the correct response operates on the environment to produce the goal object, and it is this environmental change that activates the reward-detecting afferent systems. Thus, although the reinforcement mechanism does not require efferent-to-afferent circuitry, it must recognize efferent–afferent firing contingencies and be operated selectively by them. Put another way, the operant mechanism must cause behavioral reinforcement only when the neuronal substrates of the correct response and rewarding goal object, in that order, fire off sequentially.

Up to this point, operant conditioning has been described without mentioning any stimulus which acts before the response is made. Most frequently, however, environmental stimuli may be discriminated which signal the availability of a reward if a particular behavior is performed. (The dinner bell is a familiar example of such a 'discriminative stimulus.') After extensive training with reward-signaling discriminative stimuli, goal-directed operant behaviors may become 'habitual.' Now vigorous responses with short latencies are consistently evoked by the discriminative stimulus. This observation and much other evidence, including recent work on the anatomy and physiology of the basal ganglia, support an intriguing idea – that after extensive discriminative training, reward-signaling stimuli may acquire reflex-like (response-eliciting) properties, which serve to transform goal-directed actions into stimulus-driven habits (Yin and Knowlton, 2006; Everitt and Robbins, 2005). If so, habits may be formed by a third kind of brain reinforcement mechanism, which acts by 'stamping-in' sensory-motor linkages, as originally conceived by Thorndike (1911). A similar 'stamping-in' reinforcement process also

may be operative in the learning of skills. In this case, after sufficient skill training and practice, selective reinforcement of increasingly accurate behavioral variations may assemble or link together specific motor units, which then discharge in precise and coordinated sequences.

The problem of characterizing the operant reinforcement mechanism has two main parts. First, one must identify the neurons or neuronal systems that perform the reinforcing function (reinforcing substrate). Second, one must identify the neurons or neuronal systems that are modified by the reinforcement process (target substrate). Despite species-specific constraints, which may favor some response-reinforcer pairings over others, it is generally accepted that any goal object may reinforce any behavior in an animal's repertoire. Such flexibility at the behavioral level suggests that the brain circuitry for operant conditioning is arranged to provide (1) convergence of sensory information from all goal objects to the reinforcing substrate and (2) divergence from this substrate of reinforcing output to all target or behavioral substrates. Here I shall briefly summarize the substantial published literature that has been devoted to the first question – the identification of the reinforcing substrate. Until recently, little consideration has been given to the identification of the target substrate, but it may be useful to review some initial findings and to consider the directions that research on this question may take.

Reinforcing Neurons – Brain Self-Stimulation Evidence

The idea that behavioral reinforcement is specialized neurochemically and is mediated by brain catecholamine systems has guided research in this field for 50 years (Stein, 1962, 1968). More specific hypotheses – that dopamine, norepinephrine, and opioid-peptide brain cells may serve as reinforcing neurons – extend this idea and are supported by evidence from brain self-stimulation and drug self-administration experiments (Olds, 1975; Crow, 1972; Stein, 1964, 1978; Wise, 1982, 2004, 2008). In self-stimulation experiments, animals work to deliver electrical stimulation to their own brains through permanently indwelling electrodes much as hungry or thirsty rats work to obtain natural reinforcers, such as food or water (Figure 1). In the absence of other sources of reward, the reinforcement for self-stimulation behavior must arise from the neuronal activity that is excited by the electrical stimulus. Accordingly, it is tempting to assume that some of the neurons under the electrode tip actually are the reinforcing neurons that mediate the effects of natural rewards, or at least are neurons that directly excite them.

High self-stimulation rates are observed when electrodes are implanted in regions containing dopamine or opioid peptide cell bodies or pathways. In particular, self-stimulation tightly overlaps the distribution of dopamine cells in the ventral tegmental area and substantia nigra. Self-stimulation closely follows the anteriorly projecting dopamine fibers through the hypothalamus, but it correlates somewhat less closely with the dopamine terminal fields in the forebrain. Similarly, mapping of opioid peptide sites for self-stimulation is consistent with the idea that certain beta-endorphin and dynorphin neurons are involved in self-stimulation. Involvement of norepinephrine

Figure 1 Diagram of self-stimulation experiment. When the rat presses on lever, it triggers a reinforcing electrical stimulus to its brain. Reprinted with permission from Olds, J., 1956. Pleasure centers in the brain. Scientific American 195, 105–116.

neurons in self-stimulation is more controversial. Although many laboratories report self-stimulation from sites in or near the locus coeruleus and its dorsal bundle projection, there is no general agreement that the noradrenergic neurons which make up this nucleus are responsible for the reinforcing effect. However, noradrenergic neurons in the locus coeruleus and other nuclei innervate the ventral tegmentum and provide excitatory drive to midbrain dopamine neurons. Thus, electrical stimulation of these noradrenergic sites, at the very least, could reinforce behavior via a dopaminergic pathway.

The catecholamine-opioid peptide reinforcement hypothesis also is firmly supported by pharmacological experiments. Significantly, selective antagonists of dopamine and opioid peptide receptors, such as pimozide and naloxone, respectively, reduce self-stimulation rates in patterns that resemble the extinction of behavior after reward omission (Wise, 2004; Trujillo et al., 1989). Thus, the antagonist drugs appear to act by blocking or weakening a chemically coded reinforcement message. In the disputed case of norepinephrine, selective inhibition of its biosynthesis by disulfiram and related agents decreases or eliminates self-stimulation over the same time course as the depletion of norepinephrine stores. Furthermore, intraventricular infusions of *l*-norepinephrine restore normal rates of self-stimulation within a few minutes, presumably after the exogenous transmitter diffuses to and replenishes reinforcement-relevant stores (Wise and Stein, 1969). Similar infusions of the unnatural isomer *d*-norepinephrine or

dopamine (whose stores are not depleted by disulfiram) fail to restore self-stimulation. An alternative interpretation of these results (Roll, 1970) – that norepinephrine is not a reinforcement transmitter, but acts merely to arouse disulfiram-sedated rats – has gained a widespread currency (e.g., Wise, 2008). But the arousal hypothesis is challenged by much other evidence. First, sedation itself is not adequate to reduce self-stimulation behavior; in fact, heavily sedative doses of barbiturates or benzodiazepines do not suppress, and sometimes even increase, rates of self-stimulation. Second, physical handling of the rats, priming trains of stimulation given by the experimenter, and control infusions of saline or other substances, which also produce arousal, fail to restore normal rates of self-stimulation. Indeed, even response-independent noradrenergic receptor stimulation by infusion of norepinephrine agonists (e.g., clonidine and oxymetazoline) is ineffective. The agonist infusions might be arousing, but nevertheless do not restore self-stimulation (arguably, because response-independent activation of noradrenergic receptors confuses the obligatory contingency relationship between self-stimulation responses and the electrically induced release of reinforcement transmitter).

Reinforcing Neurons – Drug Self-Administration Evidence

In self-administration experiments, operant behavior is reinforced by systemic or central injections of neurotransmitters or drugs. Of thousands of chemical substances available, animals and humans avidly self-administer only a few. These self-administered substances may properly be termed 'pharmacological reinforcers,' and it is interesting to ask why these compounds are selectively associated with behavioral reinforcement. Surely, it is no coincidence that all of the most notorious drugs of abuse (heroin, cocaine, methamphetamine, and marijuana) have the ability to mimic, release, or otherwise facilitate one or more of the natural reinforcement transmitters. Thus, many dopamine, opioid peptide, and cannabinoid receptor activators are known to support self-administration behavior (e.g., Self and Stein, 1992; Wise, 2004). In particular, agonists acting at dopamine D_1-like and D_2-like receptors, such as apomorphine (D_1/D_2), piribedil (D_2), and SKF 82958 (D_1) are self-administered. Similarly, selective agonists of mu and delta opioid receptors function as positive reinforcers as do the naturally occurring opioid peptides, beta-endorphin and dynorphin. The patterns of self-administration of many of these receptor agonists (particularly, D_1 and mu agonists) closely resemble the patterns observed when cocaine or heroin are self-administered. Hence, it is reasonable to suppose that self-administration of stimulant or opiate drugs may largely depend on their ability to activate or to enhance the activity of dopamine or opioid peptide reinforcement systems, respectively. As expected, dopamine and opioid peptide antagonists appropriately block, not only the reinforcing effects of dopamine and opioid receptor agonists, but also the reinforcing effects of stimulant and opiate drugs. Finally, a significant role for norepinephrine in stimulant drug abuse is suggested by clinical evidence – the most promising agent for the treatment of cocaine addiction is disulfiram, a selective inhibitor of norepinephrine synthesis (Weinshenker and Schroeder, 2007). Animal models of relapse following withdrawal suggest a possible explanation of disulfiram's effectiveness in patients. In disulfiram-treated rats, the rapid reinstatement of extinguished cocaine-seeking behavior, which is characteristically induced by drug-associated stimuli, stressors, or injections of cocaine itself, is greatly attenuated by norepinephrine depletion (Schroeder et al., 2010).

Self-administration methods also have been used in attempts to identify the sites of action of stimulants and opiates. In some studies, animals are trained to self-inject cocaine and morphine directly into the brain to find preferred sites for their reinforcing effects. In other studies, dopamine or opioid receptor antagonists are injected into different brain regions in attempts to block systemic self-administration of drugs of abuse. Results suggest that important sites of action for both stimulant and opiate drugs are concentrated in the nucleus accumbens, but reinforcing actions are also reported after direct injections of cocaine in the prefrontal cortex, morphine in the ventral tegmental area, and dynorphin in the hippocampus. Evidently, target sites for the reinforcing actions of drugs are widely distributed in the brain.

Methodological Caveats and Terminology

Although these anatomical and pharmacological findings support the idea that operant reinforcement is mediated by specialized neurotransmitter systems, some important problems remain. Administration of pure substances in the self-administration experiments strictly controls the chemical nature of the reinforcing injections, but because the distribution of injected transmitters to active sites cannot exactly duplicate that of naturally released transmitters, the ensuing pattern of receptor activation could be artifactual or misleading. On the other hand, although electrical activation of transmitter pathways during self-stimulation presumably releases the reinforcing chemical messenger in a relatively natural distribution at appropriate postsynaptic sites, the electrical stimulus also must cause the simultaneous release of many irrelevant transmitters and modulators. Thus in self-stimulation, identification of which cells and which transmitters are relevant to the reinforcement process is largely a matter of inference. Solutions based on mapping studies demonstrate self-stimulation in anatomically coherent systems, and those based on pharmacologic studies implicate specific neurotransmitters. However, the mapping studies often are insufficiently detailed, and the pharmacological studies can be criticized because they frequently fail to distinguish specific drug effects on reinforcement from nonspecific effects on motor performance or attention. Despite such difficulties, the dopamine–norepinephrine–opioid peptide–cannabinoid theory of reinforcement and drug addiction enjoys an increasingly widespread acceptance (for a discerning review, see Weinshenker and Schroeder, 2007). Of course, other neurotransmitters (including some not yet discovered) also may be found eventually to participate in reinforcement functions.

As used in this article, the terms 'reinforcement' and 'positive reinforcement' refer to a behavior-strengthening brain

process – the mechanism by which positive outcomes or favorable stimulus consequences increase the probability of operant responses. The term 'negative reinforcement' refers to a similar behavior-strengthening process, but one which is produced instead by the avoidance or termination of a noxious consequence. (Note: It is common to misuse 'negative reinforcement' – and to confuse it with 'punishment' – to refer to the suppression of behavior by the presentation of noxious consequences.) In the literature, positive reinforcement is often used interchangeably with the terms 'reward' and 'pleasure.' The term 'pleasure,' as used here, refers to a sweet or pleasant feeling that is experienced subjectively and thus is difficult to measure accurately for scientific purposes. As a consequence, we remain uncertain whether or not catecholamine, opioid peptide, or cannabinoid neurotransmission is required for the mediation of pleasurable feelings. 'Reward' is a term in the vernacular that may refer either to the reinforcing stimulus or goal object itself (noun), or to the process of reinforcement (verb). Its availability as a synonym of reinforcement is often stylistically convenient. Other terms, 'incentive' or 'incentive salience,' often are used to refer to neutral cues whose properties are changed in instrumental learning after pairings with biologically significant stimuli. According to some investigators, incentives facilitate behavioral performance by inducing an increase in dopamine-mediated 'motivation' or 'wanting' (Berridge, 2007; but see Wise, 2008). In any case, what seems undisputable – from research on Parkinson's disease in man and extensive related work in many species – is the crucial role of dopamine systems in movement and motor function. Evolution, it appears, has long used dopamine as a facilitator of action in animals. Accordingly, in the natural selection of a behavior-facilitating reinforcement mediator, brain dopamine may have been an obvious candidate.

Reinforcing Neurons – Electrophysiological Evidence

Electrophysiological evidence supports the idea that dopamine activity may be more directly related to behavioral facilitation than to pleasurable emotions. Schultz (2000) measured the firing of dopamine neurons in the ventral tegmental area of monkeys during studies of operant conditioning. Before training, the dopamine neurons discharged at high rates only when the food was touched or tasted. In well-trained monkeys, however, the dopamine neurons discharged rapidly just before or during the performance of the operant response, but not when animals actually ate the food. If it is correct to assume that pleasurable feelings would be most strongly evoked by the taste of the food, then, in well-trained animals, the correlation between dopamine activation and pleasure seems to weaken and disappear. Similar findings were obtained in stimulus discrimination experiments. At the start of training, reward-signaling clues did not elicit high-rate dopamine cellular responses. After many correctly discriminated responses, however, each presentation of the positive clue triggered a brief phase of elevated dopamine firing. Again, and significantly, the touching and tasting of food by these highly trained monkeys no longer excited an increase in dopamine firing rates. Schultz's results may explain how goal-directed operant actions may be transformed into habitual responses by discrimination training (as noted above, Section Three Modes of Behavioral Control – Reflex Operant, and Habit). Specifically, the shift in the phasic activation of dopamine neurons from food itself to a discriminative stimulus could mediate the neurobehavioral shift from operant response to habit. According to this idea, early in training, the food presentations activate reinforcing dopamine cells to elevate the probability of any just-completed operant response. Later in training, when food no longer excites such dopaminergic firing, the less precise operant process is deactivated. Now the habit formation process is predominant because reinforcing dopamine cells are activated only by the discriminative stimulus. This mode of reinforcement presumably stamps-in a more discerning and useful association – the linkage between a reliable reward-signaling stimulus and a well-documented correct response.

Target Neurons – Theoretical Considerations and Evidence from Cellular Operant Conditioning

As noted, little theoretical or experimental effort has been devoted to the identification of the substrate that is modified by the operant reinforcement process. What are the neuronal targets of the reinforcing neurons? Because it is operant behavior that is reinforced, it is plausible to assume that behavioral substrates are major targets. It is commonly believed that operant conditioning involves the strengthening or reorganization of complex (but yet to be identified) neuronal circuits, which presumably form the substrates of reinforceable responses. According to this conventional view, the whole response is the unit of reinforcement. However, where in the rat's brain, for example, might one find the circuit for a lever press response? And how might this circuitry change when lever pressing is reinforced? Such anatomical and physiological considerations, as well as difficulties at the behavioral level associated with response definition, challenge the idea that elaborate neuronal circuits are the functional units for reinforcement. According to Skinner (1953), a more useful conceptual scheme recognizes the ultimately continuous nature of operant behavior. In this scheme, as noted, operant behavior is construed as a stream of actions and interactions with the environment, which arises from the intrinsic activity and constantly shifting activation of infinitesimal behavioral elements. It is these elements, or 'behavioral atoms,' and not their manifestation in combination as whole responses that are the units actually strengthened by reinforcement. If so, and if atoms of behavior can be represented by the firing of individual neurons, then it could be argued that it is the behavior of individual neurons, and not of neuronal circuits, which is directly modified by reinforcing signals (Klopf, 1982).

The cellular reinforcement hypothesis has been tested in my laboratories by use of a novel '*in vitro* reinforcement' paradigm (Stein et al., 1993, 1994). The method uses training procedures closely analogous to those of behavioral operant conditioning to answer the question: Can the activity of relatively isolated brain cells in hippocampal slices be reinforced by local micropressure injections of dopamine or other reinforcing transmitters or drugs? My colleagues and I found that the bursting responses of individual pyramidal neurons in the CA1

layer are in fact progressively increased by burst-contingent applications of dopaminergic and cannabinoid receptor agonists (Figure 2). The bursting responses of CA3 units are similarly increased by dynorphin, an opioid receptor agonist. The same microinjections, administered independently of cellular activity, fail to facilitate and frequently suppress hippocampal bursting. This finding, and the observation that glutamate (an excitatory transmitter that is not associated with the behaviorally reinforcing effects of drugs) fails to increase bursting, together indicate that general stimulation of hippocampal activity is an unlikely explanation of the facilitatory action of the burst-contingent injections. Reinforcement delays exceeding 200 ms largely eliminate the reinforcing action of dopaminergic agonists. Taken together, these initial findings are consistent with the suggestion that the reinforcing actions of dopaminergic, opioid, and cannabinoid drugs may be modeled *in vitro* at the cellular level.

A Molecular Hypothesis of Reinforcement

Surprisingly, only burst firing of hippocampal cells – and not single-spike firing – is amenable to *in vitro* reinforcement. This unexpected observation led to the formulation of a detailed molecular hypothesis of cellular and behavioral operant conditioning (Stein, 1997). The model is based on the premise that the phosphorylation of L-type calcium channels is the ultimate step in the reinforcement of hippocampal bursting

Figure 2 Operant conditioning of the activity of a CA1 pyramidal cell in a slice of dorsal hippocampus with local injections of dopamine used as reinforcement. The bursting activity of the unit throughout seven phases of a complete experiment is shown. Each point shows the number of bursts in successive 50-s time samples. Prior to the first baseline phase, a burst criterion of four or more spikes was selected. This criterion gave a stable burst rate for this unit that varied between 7 and 8 per 50 s in the initial baseline period (BASE). In the reinforcement period (REINF), dopamine HC1 (1 mM in 165 mM saline) was applied for 50 ms immediately after each burst; *after an initial period of suppression*, the burst rate eventually increased to a maximum of 42 per 50 s. Following a second baseline period, the same number of dopamine injections were delivered independently of the unit's behavior as a control for possible stimulant effects (MATCH). The number of injections was matched to that earned during the last six 50-s periods of the reinforcement phase. Bursting rates were increased by contingent dopamine injections during the reinforcement periods, but were not increased when the same injections were administered noncontingently in the matched-injection period.

responses. Hippocampal bursts are made up of a few initial sodium spikes followed by a succession of calcium spikes. The sodium spikes induce a brief membrane depolarization, which may trigger a subsequent series of calcium spikes via the voltage-gated L-type calcium channels, but only if the calcium channel protein is in its active (phosphorylated) configuration. Any useful molecular hypothesis of *in vitro* reinforcement must provide a plausible explanation of the burst-dependent (response-contingent) nature of dopamine's reinforcing action. Just as in behavioral reinforcement, response contingency in cellular reinforcement is obligatory. As noted, we indeed find that burst-independent microinjections of dopamine are ineffective as reinforcements in cellular operant conditioning. According to my working hypothesis, this important observation indicates, at the molecular level, that burst-independent dopamine microinjections fail to promote the phosphorylation of L-type calcium channels.

What is needed most critically to complete the hypothesis is a molecular coincidence detector able to respond selectively to the conjunction of bursting activity (calcium influx) and dopamine microinjections (D_1/D_5 receptor activation). Interestingly, a brain enzyme has been described which exhibits the precise biochemical properties and subcellular localization required for the molecular coincidence detector. *Type VIII adenylyl cyclase* efficiently catalyzes the phosphorylation of calcium channels, and it is present in high concentrations in the hippocampal CA1 region. More particularly, it is activated synergistically by the joint action of two regulatory molecules: calcium ion and dopamine (which acts via a stimulatory G protein subunit). In the absence of one or both regulatory molecules, Type VIII adenylyl cyclase is essentially inactive. Thus, according to my hypothesis, for successful cellular operant conditioning, dopamine must be microinjected just after a bursting response (when local calcium ion concentrations are briefly elevated) to effectively activate the reinforcing type VIII enzyme. Notably, the failure of burst-independent dopamine to support cellular reinforcement has a related explanation. Burst-independent dopamine applications do not activate the type VIII coincidence detector because the requisite local calcium concentrations are insufficient when neurons are quiescent or firing only in single spikes.

The foregoing mechanism, based on second-messenger activation of L-type calcium channels, is a short-term process appropriate for temporary reinforcing effects. For long-term reinforcement effects, which presumably require new protein synthesis and structural changes, the genetic machinery of the reinforced target cells and their synapses must be engaged. Intriguingly, the same second messengers involved in the above-hypothesized short-term reinforcement mechanism – calcium ion and cAMP – can also activate the important transcription factor cAMP response element binding protein (CREB), which has long been implicated in long-term memory formation. Hence, selective activation of CREB in reinforced target cells, triggered by rises in calcium and cAMP, could plausibly initiate the new protein synthesis and structural modifications necessary for long-term operant conditioning. Recent evidence from David Self's laboratory on CREB overexpression in cocaine self-administering rats provides experimental support for this suggestion (Larson et al., 2011).

Abstract

Relapse prevention training involves the use of a set of procedures that are designed to minimize relapse following a psychological intervention. Marlatt and Gordon (1985) were responsible for developing a set of relapse prevention strategies for addictive disorders, but the approach has been extended to a broad range of psychological problems including obesity, depression, and criminal behavior. The approach includes the identification of (and preparation for) high-risk situations, rehearsal of coping skills, relapse-crisis debriefing, education, and lifestyle modification. Although there are some encouraging findings in the treatment outcome literature, empirical support for relapse prevention has been mixed and many experimental studies have methodological limitations which prevent strong conclusions at this stage.

Many psychological and psychiatric problems are characterized by a temporal pattern in which symptoms are either chronic or vary in severity over a long period of time, with oscillations between remissions and return of symptoms. Substance-related disorders such as alcohol dependence are often relatively enduring, and mood disorders typically follow the second pattern of alternating symptom presence and remission. The empirical demonstration of the efficacy of psychotherapeutic interventions requires substantiation of the long-term benefits of therapies for such disorders (*see* Psychological Treatments, Empirically Supported). Accordingly, there has been a growth of interest in the development of therapeutic approaches that are designed to minimize relapse (or, conversely, maximize the maintenance of therapeutic gains) over extended periods of time. Relapse prevention refers to a set of procedures that designed to obtain long-lasting benefits. Marlatt and Gordon (1985) published the seminal work in the area of relapse prevention, in which they described a set of relapse prevention strategies for excessive alcohol consumption and other addictive disorders. This approach applies a cognitive–behavioral perspective to the problem of relapse and involves the employment of a specific set of treatment techniques. Other researchers have focused on relapse prevention for a diverse range of problems, adapting the original approach accordingly. Empirical support for the approach has been mixed, but there are some encouraging findings in relation to some specific problems. Methodological issues in the research place limitations on the conclusions that can be reached at this stage.

Conceptual Basis of Relapse Prevention

The term Relapse Prevention (RP) has been associated with a particular set of techniques as described by Marlatt and Gordon (1985). It can be argued that any approach which has as its clear goal the minimization of relapse (or enhancement of maintenance) might be construed as RP. Few approaches other than Marlatt and Gordon's RP, however, have been embedded in a coherent theoretical framework that is intended to be generalizable across a variety of psychological or psychiatric problems. Cognitive and behavioral theories provide both the framework for the development of RP techniques and the conceptual basis for understanding why a particular person relapses and how best the problem might be ameliorated. Specifically, problem behaviors are viewed as arising from the influence of both learning principles (classical and operant conditioning) and cognitive appraisal processes (attributions, predictions, and other judgments). For example, a person's alcohol consumption is regarded as being (a) elicited by environmental cues (presence of stimuli associated with drinking such as a glass, bottle, certain companions, time of day) and (b) reinforced by its consequences (stress reduction or mood enhancement). Apart from environmental cues, a considerable amount of attention is given the role of cognitive factors in RP. Cognitive factors may include, amongst others, causal attributions or outcome expectations. Marlatt and Gordon's RP approach draws heavily upon the concept of self-efficacy (Bandura, 1977) in its theoretical foundation (*see* Self-Efficacy). Thus, methods which enhance a person's confidence that they will be able to perform the necessary behaviors and the belief that their performance will lead to an effective outcome, are thought to be the ones which are most likely to prevent relapse. A good deal of the research literature on predictors of relapse has focused on self-efficacy. For example, low self-efficacy about the performance of particular behaviors has been found to be predictive of relapse across several problem areas such as alcohol use, obesity, depression, and smoking. The underlying philosophy of RP emphasizes the notion that the maintenance period is an opportunity for the practice of newly acquired self-control strategies. Any 'lapses' that occur are viewed as being useful to provide information about the ways in which people identify, contribute to the occurrence of, or respond to, high risk situations. A 'lapse' may involve a return to the problem behavior on a single, specific occasion (or a small number of occasions), but a 'relapse' involves a repeated accumulation of lapses that approximate the level of severity of the original problem. From this standpoint, 'lapses' are seen as providing positive experience from which to draw important information that might assist in preventing future lapses, and, by implication, future relapse.

Relapse Prevention Strategies

In principle, RP procedures may be implemented at one of three different points in time, either as: (a) an integral part of the initial treatment program; (b) a discrete set of sessions that occur towards the end of treatment; or (c) a set of sessions that are spaced across a period of time after the end of initial treatment. In the case of the latter approach, sessions may sometimes be more properly regarded as 'booster sessions,' especially if the predominant approach involves a continuation of the basic components of the original treatment or the use of prompts for the person to employ the techniques used in the original treatment. Most commonly, Marlatt and Gordon's RP is viewed as an integrated treatment which focuses on the concept of prevention of 'lapses' from the outset, and continues this emphasis beyond the normal period of treatment into a 'maintenance phase.' In practice, studies of the efficacy of RP differ in the precise details of the timing of the delivery of the specific components. These components include (but are not limited to) the identification of high-risk situations, preparation for any high-risk situations that have been identified, explicit rehearsal of coping skills, relapse-crisis debriefing, education (e.g., about the effects of drugs), and lifestyle modification.

The identification of high-risk situations represents an essential component of the RP approach. For example, it might be found that resumption of alcohol consumption occurs when the person has had a clash of opinion with a colleague or manager at work. A list of idiosyncratic high-risk situations can be obtained, based either on knowledge of the person's previous history or on the responses to self-report inventories of typical situations in which the person is asked to indicate (a) how often these situations occur, and (b) how difficult it is to engage in the desired behavior or not engage in the undesired behavior when such a situation arises. In the case of cigarette smoking, typical high-risk situations could be (a) having a cup of coffee; (b) sitting down to study at the desk; or (c) seeing someone else smoke. Learning to recognize that a high-risk situation is occurring or is imminent is a crucial part of the RP approach. People are taught to recognize the importance of 'apparently irrelevant behaviors,' exemplified by the gambler who chooses to drive home from work via a more scenic route (justified by the better view) when the route just happens to pass the casino. On the other hand, other high-risk situations may be more obvious, even to the individual, such as the person who travels business class by plane and is, therefore, likely to be offered free alcoholic drinks. RP is also connected with the concept of the 'abstinence violation effect.' This effect is thought to underlie the occurrence of a relapse in a person who has merely lapsed by breaking a preplanned limit on daily alcohol or cigarette consumption. It is argued that once a person has broken the limit, they may fail to exert any further control over their behavior. RP decreases this emphasis on 'rule violation' by focusing on self-control and deriving useful information from the occurrence of any lapses.

RP involves teaching people not only to identify such situations as risky, but also to prepare themselves for reducing the likelihood of a lapse. Simulations of high-risk situations can be used to provide opportunities to practice behavioral responses under supervision of the therapist. Many relapses are thought to occur following the occurrence of negative emotional states such as anger, depressive mood, and anxiety. Thus, RP involves the identification of such emotion–behavior linkages and the use of cognitive–behavioral strategies for the management of these negative states. Other lapses may be triggered by interpersonal conflict and may necessitate a heavier therapeutic focus on helping people to develop better communication and interpersonal problem-solving skills. In the case of addictive behaviors, there may be social pressure to engage in smoking, drinking or other drug taking. Preparation for dealing with such social pressure through assertiveness training may be incorporated into the treatment. Lifestyle modification is also employed in order to increase the frequency of engagement in pleasant, relaxing activities that may also be incompatible with the addictive behaviors.

Efficacy of RP

RP has been the subject of a number of experimental evaluations since it was first proposed as a treatment for alcohol and other addictive problems. Wilson (1992) reviewed the existing RP literature in the areas of alcohol problems, smoking, and obesity. Carroll (1996) also published a review of RP to a wide range of problems. Twenty-six studies, on substance use only (covering the years 1978 to 1995), were the subject of a meta-analysis conducted by Irvin et al. (1999). Even before considering the results of the empirical literature, the point needs to be made that there is surprisingly little research published on RP despite its presence as a concept in the treatment-outcome literature for about two decades. The drawing of firm conclusions is hampered by this relatively small body of literature, especially given the diverse types of psychological problems to which RP has been applied and the variety of procedural modifications that have been made in the published studies. A second cause for concern is the relatively short length of follow-up periods, especially given the explicit focus on relapse as an empirical issue. While it is likely that maintenance diminishes as time increases, and this appears to be the case (Irvin et al., 1999), it is not clear what type and level of resources need to be put into RP-based therapeutic endeavors to bring about meaningful results in the public health sense. With these, and other limitations in mind, the following tentative conclusions can be drawn.

The earliest controlled studies of RP were conducted on alcohol problems and it continues to be the main focus of attention for RP researchers. Varying degrees of success have been reported for RP in these studies. A number of methodological explanations may be offered for some failures to find differences between RP and control groups in some studies, including low statistical power, ceiling effects associated with the success of the initial intervention, the brevity of the follow-up, and the sharing of common elements in the treatments. Irvin et al. (1999) conclude that, amongst the substance use disorders, the strongest positive effects for RP have been found for problem drinking, although even within this group of studies, the outcome variable that is associated with the best response is psychosocial adjustment rather than drinking behavior *per se*. Like problem drinking, relapse rates following

smoking cessation programs are notoriously high. While some success has been achieved using booster sessions, these effects frequently are lost after the eventual termination of the booster sessions. Studies of relapse prevention strategies for smoking cessation have also yielded inconsistent results. In their meta-analysis, Irvin et al. (1999) draw attention to the relatively poor outcomes with RP in the area of smoking cessation. It should be noted that a few studies have been conducted on RP for illegal drug use. Cocaine use has been the subject of a small amount of research. As with smoking, evaluations of RP for these addictions have not been noted for their successful outcomes. Irvin et al. (1999) also conclude that the effects for these problems are weaker than those for alcohol problems.

The maintenance of weight loss following cognitive–behavioral treatment was the subject of a series of studies reported by Perri and co-workers in the 1980s (see Perri et al., 1992). In this research, behavior therapy plus relapse prevention training and contact after treatment produced the largest effects. Despite the sometimes positive outcome of longer-term treatment for obesity using adaptations of RP approaches, it is clear that the overall gains associated with treatments for obesity are often modest and that many people regain the weight loss during an initial treatment period.

Other psychological problems for which an attempt has been made to develop and evaluate RP approaches include depression (Wilson, 1992) and sexual offending (Laws, 1989). Although it is well established that relapse following an episode of depression is as high as 50 percent over a two-year period, there has been little systematic exploration of specific, psychologically informed RP methods for this problem. It is possible that focus on RP for some types of problems such as depression is misdirected because the major impact on maintenance may be derived from the potency of the initial cognitive–behavioral intervention.

Methodological Issues

There are several methodological problems in the study of RP and its effectiveness. RP clearly is concerned with long-term maintenance, but the relatively brief length of follow-up periods in many studies places some limitations on the conclusions that can be drawn. The RP approach contains a number of specific components, but these components are not necessarily employed in all studies and it is not clear which components are necessary for the best outcome. In many studies, RP procedures have been mixed into a broader treatment, making it difficult to separate the effects of RP from those of other components. With some problems, such as depression, it would be preferable for research on RP to be conducted using samples of people who are at high risk for a subsequent episode rather than for all people who complete an initial intervention. In some studies, especially when the RP is being delivered following the completion of an initial broad-based treatment approach (e.g., cognitive–behavior therapy for depression or anxiety), there is a need to separate initial treatment responders from nonresponders. There is little point in examining the impact of a post-treatment RP on nonresponders to an initial treatment program because they have yet to demonstrate responsiveness to treatment. These methodological issues pose particularly difficult problems for which the solutions are generally costly and time consuming to implement.

Conclusion

Despite nearly two decades of research on RP, the research produced has been quite meager and many questions remain to be addressed or resolved. The studies of RP for any given problem are so few in number that it is difficult to draw any firm conclusions at this stage. Scattered through the literature, there is some encouraging support for RP in relation to alcohol-related problems, but strong conclusions are limited due to methodological shortcomings and the relative scarcity of studies. There is a need for a large-scale evaluation of RP with addictive disorders. There has also been some progress on the development of techniques for other problems such as obesity, depression, sexual offending, and health problems.

The field of RP research may benefit from greater attention to improving our understanding of the specific ways in which RP affects basic psychological processes (i.e., investigations of the mechanism of change). Further research is also needed on both general and problem-specific predictors of relapse for particular types of symptoms so that the RP approaches can be tailored more specifically to suit the features of specific disorders. The timing of the implementation of RP procedures also needs to be considered in relation to knowledge about the temporal patterns of symptom presence and remission that are characteristic of different disorders. Continued efforts to refine and develop novel variation on RP approaches to chronic mental health and physical problems should remain a high priority for research.

Editor's Note

Since Wilson's essay was first published, the treatment community continues to search for evidence of successful relapse prevention strategies in areas such as nicotine cessation, weight loss, alcohol abuse, and others. What Wilson wrote 15 years ago, remains true today: "Despite nearly two decades [now nearly four decades – JDW] of research, the research produced has been quite meager and many questions remain to be addressed or resolved."

For a recent review of evidence-based relapse prevention approaches, see Witkiewitz and Marlatt (2007). A useful review of nicotine-cessation relapse prevention research is by Hajek et al. (2013). In the case of alcohol and drug relapse, a similarly useful review is Hendershot et al. (2011).

Two relatively recent emphases in the research literature are pharmacological strategies for relapse prevention in alcohol abuse and 'mindfulness' as a prevention approach. On the former, see Spanagel and Vengeliene (2013). 'Mindfulness' derives from Buddhist meditation practices and involves focusing the patient's mind to accept one's experiences (of craving, withdrawal, anxiety, etc.) but to recognize 'mindfully' that all such conditions are transient or impermanent. The use of the strategy in relapse prevention for substance abuse is described in Witkiewitz et al. (2013); for depression, in Piet and Houggard (2011); for smoking, Brewer et al. (2011).

Relational Social Work

Fabio Folgheraiter, Università Cattolica del Sacro Cuore, Milano, Italy

Abstract

Relational social work is a paradigm for which the process of existential problem solving, in whatever setting it takes place, presupposes free encounter and synergy among diverse individual efforts and points of view. It is not the outcome of unidirectional cause–effect intervention. According to this conception of welfare, well-being is not achieved through the manipulative procedures of welfare professionals and systems. On the contrary, it maintains that freedom of cognitive elaboration and the serious commitment of people in community networks can be crucial resources for the functioning, and the purpose itself, of welfare organizations and policies.

Introduction

It is a given that there were innumerable effective helpers – some of them extraordinarily skilled – in the long prescientific past of humanity. Although in itself banal, this is, nevertheless, surprising, almost inexplicable, to modern eyes. If social work is considered, like other modern professions, it would consist of the direct application of scientific knowledge to the problems of human life, making it difficult to understand how a substantial core of helping practices could exist long before the advent of modernity. Nor can one understand – after more than a century of constant technical scientific and managerial progress – why social work today is at risk of deteriorating and regressing rather than improving (Lymbery, 2001; Marston and McDonald, 2012; Rogowski, 2010). Social problems have been made increasingly interconnected and extensive by globalization (Dominelli, 2010), but they are no more severe than they were at the beginning of the profession (Bortoli, 2012). Nevertheless, today's social work seems more uncertain and debilitated than it was at that time (Bamford, 1990; Folgheraiter, 2012; Jones, 2012).

'Relational social work' (Folgheraiter, 2004, 2007, 2011) is a new approach to professional practice that harmonizes these two contradictory sets of evidence. Among the many possible causes of the current crisis, the relational paradigm points to the 'hidden vice,' which has gradually become embedded in the collective unconscious – as Jung would put it – of professional practice, namely, an ever greater technicism (Dominelli, 2010). Like other welfare professionals, social workers have been induced to overestimate the capacity of scientific knowledge, and then of objective procedures, to produce (or repair) social well-being. They have neglected other formidable logics of care that have existed and have fortunately persisted beneath the structures – even the rubble – of modernization. However, the relational paradigm conducts this critique with caution. The role of scientific power is rethought rather than rejected, because rigorous scientific reflection can reveal the limitations of positivist technoscientism in the human professions.

Copernicus understood that it was necessary to reverse the fundamentals of classical astronomy to explain celestial motion. He succeeded in this endeavor by recasting the role of the human observer, whom he ideally located outside the stellar system, and therefore no longer on an Earth conceived as the center of the universe. The relational paradigm does largely the same thing in that it no longer places the professional expert, with his or her exclusive abilities, at the center of 'clinical' action (and 'diagnostic' observation). At the same time, neither does it center on the so-called help recipients envisaged by the famous 'client-centered' approach developed by Carl Rogers (1951). The relational theory locates the crux midway between the professional social worker and his or her interlocutors based in 'lifeworlds' (Husserl, 1959) – that is, in the human communities where people and families live and interact.

Theoretical Bases and Key Concepts of the Relational Approach

As its name suggests, the relational paradigm considers helping (and the consequent well-being) as a largely imponderable process arising from well-intentioned social relations. This definition highlights the ethically driven nature of social work, which is conceived as a profession that accompanies the 'free doing of good' in human societies. One accordingly understands that this relational conception does not coincide with the well-known systemic approach of family therapy (Minuchin, 1974; Pincus and Minahan, 1973; Selvini-Palazzoli et al., 1978), which also emphasizes social relations but does so negatively and somehow mechanically (Seikkula and Arnkil, 2006) by viewing interpersonal relations as 'encysted' causes of social problems that must be repaired with specific action. Nor should the relational approach be confused with 'relational psychoanalytically informed social work' (Ornstein and Ganzer, 2005; Pozzuto and Arnd-Caddigan, 2006) which, as the name suggests, is based on a clinical matrix extraneous to the essence of the social logic of helping (Folgheraiter, 2012). The core concept of the relational approach is a nonintuitive idea of the social relationship developed in the sociological reflections of Donati (2010, 2011) and in all the principal human sciences, especially philosophical (Levinas, 1961), economic (Sen, 1980), and anthropopedagogical (Illich, 1973; Nussbaum, 2006).

Respecting Otherness

For every person, who is, nevertheless, irreducibly alone, being at ease in the world during the life journey is conditioned by the

encounter with the 'other,' Levinas writes: "We are surrounded by beings and things with which we maintain relationships. Through sight, touch, sympathy and cooperative work, we are with others" (Levinas, 1979: pp. 15–16). Realizing that the humanity of others is bound up with one's own – understanding that there is a meaningful bond between people – is to become aware that individual lives also have sense external to the self – that is, the function of social responsibility (Jonas, 1979). Perceiving 'sense' for oneself is synonymous with achieved well-being (which literally means 'feeling well in oneself'). But that sense arrives when one's being goes beyond itself and 'overflows': I am entirely well only when I open up and become 'my brother's keeper' (Bauman, 2000). In so far as I feel that I live beyond my mere functioning, I am a moral being (Barnes, 2012; Sevenhuijsen, 1998; Tronto, 1993) and I am proud of my identity.

Nevertheless – Levinas maintains – "all these relationships are transitive: I touch an object, I see the other. But I am not the Other" (Levinas, 1979: pp. 15–16). There is a minimum of two beings involved in every relationship, and by definition, they are distinct: they remain what they are in essence. In their encounter, they remain, as Levinas puts it, 'the same.' If the outcome were a merger or incorporation between them, a molding of the one to the other, the relationship would be dead. Levinas again writes: "If one could possess, grasp and know the other, it would not be the Other." Levinas takes this principle to its extreme: even the simple endeavor to know the other, because of mere desire for knowledge or functional purposes (e.g., to make a diagnosis), is subtly to pollute the relationship (Rossiter, 2011). "Knowledge is always … assimilation … with everything that goes with the 'prehend' in 'comprehending'. The most audacious and distant knowledge does not put us in communion with the real other; it does not replace sociality: it is still and always solitude" (Levinas, 1982: p. 75).

Turning to social work, or more generally to every personal helping process, it could be said that a relationship undertaken with the praiseworthy purpose of changing the other for the better, or with the intent to make the other 'conform to my idea' of him or her (Levinas, 1982), puts the social worker in a state of solitude as a 'solver.' A certain distress, at times even a burnout, results from the impossibility of being in authentic contact with the person being helped. Although this is formally the 'object' of social work, he or she is a subject. There is always an element of violence in every technique applied to the helpee, and this lack of respect clashes with relational principles. The technique undermines the effectiveness of helping processes by suffocating both the practitioner's and the recipient's energy. It produces conditions in which difficulties tend to 'decay' rather than produce real change (Hare, 2004). If, however, a technique proves effective in what Luhman calls 'people processing,' the other is reduced to a 'thing' and is therefore degraded as a human being. He or she would be unknowingly or unwillingly violated in his or her essence, in exchange for having achieved or perhaps reacquired some better functionality. These are not just academic hypotheses or logical considerations: consider, for example, behaviorism, or Skinner's lucidly delirious *Walden Two*. With the sincere intent to 'do good' (but also at the bottom, to 'clear up' a unilaterally defined disorder in the other person's life), the technical intervention generates malaise and expands it.

Relational social work neither consists simply in being good hearted nor is it merely action to produce a generic pleasantness in human contacts. Even less does it involve the use of strategies or tactics in human relations. Social workers may try to be pleasant and empathetic with their users because this is what theories tell them to do. But they often act in this way for the covert instrumental purpose of asserting their will. It is convenient for the expert to be polite when entering the world of others because this induces the trust necessary in the latter so that they behave as the expert wants. A professional of this kind resembles more a huckster or even a cheat – although, of course, acting in good faith – than a social worker.

In short, the first, and counterintuitive, principle of relational social work is that social problems may often have solutions, but they can never be 'solved.' People may change (as they constantly do) but they cannot ever 'be changed' (Prochaska et al., 1992). A social worker is not allowed to manipulate people so that their lives comply with want she or he wants them to be (Seikkula and Arnkil, 2006; Folgheraiter, 2004). (It is not allowed either methodologically – because in this way the intervention does not work – or ethically – because in this way the principle of self-determination is violated.) No professional can unilaterally eliminate problems in other people's lives just because she or he knows what needs to be done. Nor is this possible even if the expert shrewdly adopts the tactic of associating with other colleagues in a 'multidimensional team' – which is like forming a phalanx to deal with social problems. The expertise derived from scientific knowledge is only one of the factors – and not the most important – in determining the effectiveness (measurable or otherwise) of professional helping practices. When concluding a technical social work intervention, a certain effectiveness has come about notwithstanding the exercise of that technicality. It has occurred because the two people involved in the relationship have 'taken each other by the hand' and together generated – each remaining distinct – a certain additional human energy (greater than the sum of the energies of the two parties), which gradually, and unpredictably, alters the situation and produces the shared value that Donati calls a 'relational good' (Donati and Solci, 2011).

Reciprocity and Relational Empowerment

A second principle, which is also counterintuitive, is that generating well-being in complex existential situations requires each person involved to leave the role of user or client (i.e., the role of manipulated) to assume that of therapist or helper (Folgheraiter, 2000). When one is immersed in a compromised or objectively destabilized (and destabilizing) situation and begin a process of recovery that eventually makes one feel well, it is always because one has been able to exit from himself or herself as an individual beset by problems, and because one has been able to perform a useful and wide-ranging role. As long as one considers oneself a victim assisted by superior beings – however, compassionate or, as denounced by Ivan Illich (Illich et al., 1977), conceited or self-interested – one will never be able to 'feel well.' The

principle of reciprocity (or of parity or mutuality) – which is the core of the relational approach – states that users can receive true help (as prescribed by their role) only if they can give themselves to those from whom they accept it (Freeberg, 2007; Petterson and Hem, 2011). Likewise, social workers can give help (as prescribed by their role) only if they know how to ask for and receive it, primarily from their 'needy' interlocutors. Literally, 'helping relation' means that the help arises from a relation: that is, from a synergy between two or more agents engaged with equal commitment and dignity in achieving shared improvement (Folgheraiter, 2004).

This claim recalls the concept of relational empowerment. This is a rebalancing of therapeutic and manipulative power in which the party with most of it (generally the professional practitioner) cedes some to the less empowered interlocutor so that she or he becomes more autonomous and active in dealing with the situation. This operation is not zero-sum. The power surrendered is not lost but 'invested' in social relations so that it yields high-interest returns for the social worker.

Self-Help and Mutual Help

Another important principle is that of self-help. The assumption of responsibility for others has an automatic beneficial effect on the person who offers the help, in conformity with the helper therapy principle (Riessman, 1965), which says that, when I help another person with a problem, I also help myself. But there is a deeper lying relationship involved: that with oneself. The Alter for whom responsibility is assumed by a certain Ego may coincide with that same Ego. This happens whenever an Ego that feels inadequate decides to become different from what it is now (i.e., to change). In this case, we may say that Ego enters a relationship with an otherness (other from the self), which is what Ego wants or hopes to become. Ego enters a relationship with his or her life by cognitively observing it from outside as if it were another person's life and reflexively interacting with it (Archer, 2003). In this internal game of mirrors, the person motivated to reorganize his or her life – to 'redesign' it (Ferguson, 2001) – works on himself or herself, but this self-generated impetus may take the person out of himself or herself toward truly 'external' relationships. If a person is motivated to change (Prochaska and DiClemente, 1982), and if the dynamic of that expected change is effectively triggered in that person's life, by definition, she or he takes responsibility for himself or herself simultaneously with taking it for others. By assuming responsibility for others, that person simultaneously accepts that others assume responsibility for him or her. This reciprocal reliance of persons on one another is what is commonly called 'mutual help.' At its basis there must be trust, which is the 'glue' of social relations and which, by cumulating, creates what is generally termed 'social capital' (Folgheraiter and Pasini, 2009).

The Coping Network and Its Freedom of Action

Action directed toward other persons constructs relational patterns of varying complexity. If they are truly dialogical and not merely functionalist meetings of various kinds (like those of the above-mentioned multidisciplinary teams, or case management panels, or technical planning boards), we may call them 'coping networks' (Folgheraiter, 2011). A network is – to use Levinas's expression – a "pluralism which does not fuse into unity" (1979: p. 15): a pluralism of voices and intentions in which each is respected, a contrivance that does not attempt to coordinate or hierarchize or to impart orders or engineer individual abilities, and so on. A network is such when the dispersed units of which it is composed (people in the present case) interact without 'condensing' to become a coherent 'whole.' In a network, there is no preestablished coherence but freedom (Sen, 1999), indeed a freedom squared, of higher order, because it is the amplified result of multiple freedoms. The only coherence, if everything goes well, is with respect to the coping aim that unites all the network's members in its pursuit. In social work practice, aims are by definition profound and broad because they involve the entire lives of the people in the network. They are, in Archer's (2007) terminology, 'ultimate concerns.' The freedom and creativity that spring from the unpredictable are therefore necessary if one is not to remain caught in *ex ante* schemas, which may be intelligent but are more often proved wrong by concrete experiences.

The greatest degree of freedom is perhaps given by a certain degree of 'ignorance.' Not having the initially precise knowledge that constrains future action is, paradoxically, 'freedom.' More specifically, when the lack of knowledge is due to pure negligence – that is, if the precise knowledge is available but not known – that lack is deplorable. But when the knowledge does not exist, and cannot exist, or when it exists in abstract but has no reference to the specific contingency, then admitting ignorance is not just an honorable surrender. It is a necessary strategy.

Pretending to know is the frequent unconscious bluff pulled by modern experts. Admitting *not* to know like Socrates, as the necessary premise for mobilizing every resource in search of a truth or a certain good, is the authentic moral (and therefore operational) basis of social work. The term 'coping' denotes the effort made to resist and actively combat an evil without knowing 'how to do so' in advance. By managing as best as they can, but with an open mind, all the network's members hope to learn together along the way (Folgheraiter, 2011).

Methodological and Technical Principles

According to relational theory, therefore, a social worker is a professional who seeks to produce as yet unknown solutions by associating the people motivated to seek them. She or he endeavors to create or strengthen trusting relations that are sufficiently 'intimate' and profound to help her or him to pursue the elusive aim that she or he is paid to achieve: the 'creation' of human well-being. In negative terms, a social worker who merely redistributes the standard provisions of an organized welfare system is not a relational practitioner. The classic functions of redistribution and social control are important, but they can only be effective if they are performed 'relationally': that is, by creating and supporting associated and cooperative action among the subjects involved (Folgheraiter and Raineri, 2012).

The Facilitation of Coping Networks

Social ties, still *weak* in Granovetter's (1973) sense, can create well-being in two ways. They can do so in all those circumstances in which suffering is due to loneliness and marginalization, so that the expected well-being coincides entirely with some form of conviviality (Illich, 1973) or sociability (Donati, 2011). Or they can do so by generating transformative agency (Archer, 2003). If the aim of the associated action is to produce more than mere sociality (more than just 'being together') and people must rearrange or change the organization of their lives, networked social ties – besides providing the protective nourishment that is social support – make it possible to engender the additional mental strength necessary to remove chronic problems. This requires cohesion, determination, and courage; but above all, it requires original thought, which may conflict with the everyday routines that have caused the malaise. This both disruptive and constructive reflexivities develop through the action that Habermas (1981) calls 'communicative' but that in social work is better termed 'dialogical' (Seikkula and Arnkil, 2006).

An Optimistic Look Forward

In general, therefore, relational social workers are facilitators of human relations – expressed in networks with varying degrees of organization – able to produce the ethically directed thought typical of every deliberate coping action. Their work is second hand, so to speak: they do not act directly, but instead facilitate the action of others. By acting in this way, a social worker does not look back to identify the causes of present dysfunctions. The worker looks forward to an open future and guides/stimulates people to do likewise. A clinical expert must take time to look backward in order to define a problem objectively and determine its causes. A relational social worker regards this determinism with a certain detachment: the worker connects with the malaise and seeks to make it the focus of the raw and approximate human energies able to cope with it. This is not a 'negative' or 'malignant' approach (Kitwood, 1997) intended to emphasize negativities and almost sadistically bring them out in the open. Rather, the relational social worker seeks to fluidify the positive elements embedded in difficult or deteriorated situations, however scarce they may be.

Who Are the Members of a Coping Network?

Relational social workers interact with networks in two ways: they either seek to catalyze them *ex novo* if they (formal coping networks) do not yet exist or they approach them when they have already formed spontaneously (natural coping networks). In both cases, the most common maneuver is to gather the persons concerned around a table and accompany and support them so that each has a voice and open dialogue can develop (Seikkula and Arnkil, 2006; Morris and Burford, 2007). But who should be invited to these reflexive meetings in which each participant is on a par with the others? The answer – easy to say, but more difficult to put into practice – is this: all those who, in various capacities (users, caregivers, neighbors, volunteers, citizens, social workers, social service managers, and policy makers, among others), are already involved not in the problem as such, but in the will to cope with it (Hall et al., 2012; Raineri, 2004).

Being involved in coping with a problem means first, being able to perceive it. At times, the people involved in serious problems do not see them or deny their existence. They are, therefore, subjectively extraneous to those problems, even though they suffer from them. Second, it means that they must be worried about the problem, seeing it as an evil for themselves and wanting to eliminate it. At times, people see an evil but feel that it is none of their business. Third, it means having the internal motivation or the mental strength to address the problem (Bandura, 1997). At times, people worry about a situation and consider it their business, but do not believe that they are able to do anything about it. In conclusion, we may say that the human resources that the relational social worker looks for in distressful situations and – having found them – gathers around a table so that they can help him or her address their shared problem through discussion are those summed up in the broad concept of 'care.' Relational social workers are experts in discerning that evanescent 'essence' within others and within themselves. Their assessment skills are concentrated on identifying not so much the canonical 'needs' or 'risks' as the people willing to engage in first person in the quest for their common good.

What Does a Facilitator Essentially Do?

A facilitator gathers the motivated people together and, on an equal footing, encourages them to interact and take decisions. To 'facilitate' is not to lead, coordinate, or command. A facilitator accompanies the action of these people and supports them in all the displays that she or he deems able to mitigate the problem. Even more so, she or he must be able to support action in directions that she or he would never have envisaged alone. A relational social worker sometimes sees the emergence of decisions or opinions that she or he thinks are wrong or ethically debatable. But as she or he is also a member of the network, although performing the role of facilitator, she or he does not directly dispute those decisions or opinions. Rather, she or he 'acts as the devil's advocate' by stimulating further and better discussion on the matter. In all these cases, the social worker does not provide answers and does not give advice – not even when requested to do so – but provides reflexive feedback by referring to the network everything that she or he sees happening to it and that instead the network does not perceive. The most important elements to monitor during a network session are the dominance of one particular personality or the marginalization of another, reluctance and fear to talk, covert or overt conflicts, the loss of logical coherence, time-wasting chatter, and so on. In all these cases the facilitator, by using the basic techniques of narrative counseling (Parton and O'Byrne, 2000; Milner and O'Byrne, 2002), refers what she or he observed to the network so that it addresses every single issue.

A Graphic Representation of Relational Coping: The Social Pentagram

In a network, multiple free agents express themselves with their own voices and their own visions of an open future. All together,

they may express themselves with a single voice. A social worker who wants to support a relational process of this kind may need a conceptual tool that visually represents it, for instance, the one shown in Figure 1. Because this scheme is constructed on five coordinated logical elements, comparing social action to a musical melody, it can be called the 'social pentagram' (Folgheraiter, 2012).

Time

The first element of the scheme is the time axis pointing out the moment (t_0) when the relationship between the facilitator and the coping network starts. The abstract scheme shows that the coping process moves toward the future and never has a rigidly preestablished conclusion – as indicated by the symbol t_x, suggesting that social coping is indefinite (and therefore not amenable to managerial control). An effective coping process may require just one meeting or even 20 of them: the facilitator is free to optimize this variable as matters proceed.

The Shared Aim

The second element of the scheme is the aim of the coping process, which is the unifying cognitive purpose present – more or less clearly – in the minds of the network's members. It is the desirable state that is the reverse of the problem whose solution the network is seeking. The need to foster the maximum freedom of expression of the people concerned, and therefore their creativity, entails that the aim must be formulated in 'open' and broad terms. If the aims of professional social work are specific and circumscribed, then strictly speaking, they are objectives rather than aims. Objectives can be achieved through technical actions, that is, through chains of preestablished acts. In the case of coping, however, situations are by definition broader in their extent because they entail changes in the life courses of all those involved. Belonging in this 'open' category – in which people associate together and are free to set their own aims – are the three standard levels of social work: the management of particular situations (casework), the activation of social or self/mutual-help groups (group work), and the organization of community projects (community work).

The Network of Motivated People

The third element consists in the set of people in relation involved in the network's action. As said, they are comprised in the ideal 'container' represented by the small innermost circle in the scheme, because they are worried by the problem and motivated to attain the shared aim. By definition, the elements of a coping network are always physical people in flesh and blood, not 'abstract' things like services or organizations. Although different, they all have equal right to free speech and free reflection.

The Facilitator or Relational Guide

The fourth element of the scheme is a facilitator willing to support and accompany the network as it progresses toward achievement of its aim. The facilitator is not only an external observer of the network but also an internal member if we consider a larger network comprising a member able to conceptualize the unitariness of an associated action that is itself fragmented. This broader network capable of self-observation is represented in the scheme by the large external circle. This is called the 'formal coping network' to indicate that, because it has a facilitator (although it remains free and fluid), it is a more structured and organized entity. The two-headed arrow connecting the facilitator with the network indicates that the facilitator does not command the network but instead relates to it.

The Surrounding Environment

The fifth element of the scheme is in fact external to the dynamic of action. It generically represents everything that is in close contact with the relational coping network and affects it, for better or worse, but does not belong to it. Significant elements in this 'environment' are the various people somehow connected to the problem, even if they are not actively involved in coping with it. Some of these people may be obstacles to the shared action (e.g., a manager who

Figure 1 The social pentagram for relational social work about here.

disapproves of discussion meetings among families who have children in child protection); others may be potential resources (e.g., a disabled man's brother whom he currently does not look after). Other elements are laws, procedures, and guidelines, as well as the prejudices and inertias of institutions. All these are structural conditionings that the network's otherwise free action must somehow take into account – although the network may sometimes act to mitigate such conditionings or even, if necessary and possible, demolish them.

Abstract

Cognitive relativism is the (philosophical) position that claims there are no absolute standards against which knowledge claims can be calibrated. Two key aspects of the relativist position are: (1) epistemological skepticism regarding a realist understanding of knowledge claims, and (2) acceptance that competing theories can be incommensurable. Linguistic monism, a position that holds that the world is constituted in and through discourse, is rejected. Instead a minimalist realist position is proposed that holds that the 'world out there' has independent causal effectiveness. Skepticism is maintained about our theories telling the truth about it. The caprice problem is tackled in terms of the political constitution of science. Relativism begs the question, relative to what? Are knowledge claims relative to a group of experts or civilization as a whole? Science as reason's exemplar is a specifically Western institution. The hostility of Islamic traditionalists toward Western rational science is explained in terms of encroachment of the realm of divine authority and usurpation of Allah's authority. In Islam, any legitimate knowledge endeavor must be premised upon and prefaced by transcendental truths. Hence, unlike the Western tradition, within Islam man's inherent ratiocinating capacities can never be a legitimate source of knowledge.

Introduction

Cognitive or epistemological relativism claims there are no absolute standards, criteria, practices etc. against which knowledge claims can be calibrated to assess their truth value. The only viable way to access knowledge claims is relative to a theoretical framework or practice. Apart from vague general statements such as 'knowledge is whatever the norms of the local culture believe it to be,' no agreement ever emerged as to what the unit of analysis should be to which knowledge claims are said to be relative. In part, this reflects the negative nature of the position itself: the rejection of the basic conviction that there is or must be some permanent, ahistorical matrix to which one can ultimately appeal in determining the nature of knowledge, truth, reality, or rationality – a position best christened absolutism. Because the dominant temperament of our age is fallibilistic, the position can also be referred as objectivism.

Critics of cognitive relativism in general are philosophers of knowledge – philosophy of science is included here – who try to construe an ahistorical matrix from which all evaluation of knowledge can proceed and support this find with the strongest possible reasons. Their worry is that unless such a matrix is found to ground philosophy, knowledge, or language in a rigorous manner, radical skepticism cannot be avoided. Given the self-proclaimed job description of philosophers of knowledge as guardians of truth, rationality, and objectivity, it should not come as a surprise that much of their energy is spent on reigning in what is deemed the precarious nature of the cognitive relativist's position. To its critics relativism seems to imply an 'anything goes' stance on knowledge – there are no defenders of relativism who ever claimed such a silly position – and hence is looked upon as a poor man's epistemology. All they claim is that there is nothing to be said about either truth or rationality beyond descriptions of the legitimate procedures of justification a given society uses in an area of enquiry.

Proponents of relativism in general are empirical-minded students of knowledge practices who take as their starting point the anthropological truism 'that elsewhere things are different' and argue that knowledge practices are no exception. The unfortunate effect of this deep and long-running split is that the at times highly charged exchange between the two groups has generated more heat than light. The contours of some kind of understanding between the two have remained mainly in a zone of shade obscurity.

Critique of absolutism normally takes either of two forms:

1. The criteria set to evaluate knowledge practices cannot be met – basically because they are set too high – which is the classical skeptical take on this issue.
2. There are culturally specific assumptions underpinning the idea of absolute criteria – originating within the Western intellectual tradition – implying that the position the philosophers defend is a culturally specific one.

Prima facie, the latter kind of critique is the more fundamental because it is a direct challenge to the integrity of a transcendental realm of the philosophical a priori on which so much philosophical thinking depends.

Epistemological Skepticism as the Basis for Relativism

Skepticism as a matter of course does not involve a substantive and constructive position of its own. It is parasitical on the opponent's position. In the context of the cognitive relativist's position, this raises the crucial question 'Skepticism with regard to what?' If knowledge practices differ across time, place, and culture, as clearly anthropological and historical studies suggest they do, the skepticism it yields seems to be directed toward a realistic understanding of knowledge claims. Realism understood here as the claim that our (scientific) theories are able to pick out the building blocks of the 'world out there' is

made of. Beware, however, that (scientific) realism is a double-barreled position and consists of two separate claims: (1) there is a world of objective reality that exists independently of us, and (2) this independently existing world has a determinate nature that is within reach of our cognizing powers. Central to this double-barreled or maximalist position is the correspondence theory of truth. The minimalist position preferred by relativists only acknowledges the existence of an independent ontological realm – a realm about nothing much substantive can be said except that it exists. Applying Ockham's razor suggests this independent ontological realm is redundant. But is it?

In its most extreme form relativism presents itself as linguistic monism: *il n'y a pas de hors-texte*. The reasoning behind the claim that 'there is nothing outside the text' is: the 'objective world' is constituted in and through discourse that there is no reality independent of the words (text, signs, documents, and so on); the organization of discourse is the object. If discourse and object are identical then it is tenable to say that the collection of words acquires a currency in discourse, which creates a referent in the real world. But is it tenable to say that real worldly objects are created by virtue of a discourse? After all, by drinking water there is a chance of satisfying thirst – with accounts of drinking water, there is not.

Another way to see the implausibility of the linguistic monistic position is to ask the obvious question of why people go to such extraordinary lengths to find out how the 'world out there' reacts to all kinds of experimental interventions. The independent causal effectiveness of the 'world out there' seems a pretty good reason. Implied in this argument is that this independent ontological realm isn't redundant after all. The causal effects of the whole in the ozone layer don't disappear when we stop talking about it! Sure enough it is correct to say that people actively have to intervene in nature to come up with some kind of knowledge about it. However, it is quite another thing to say that all there is to the world is how it gets wrapped up in a web of significance spun by them. In short, it does not follow from this that the *phenomena* scientists investigate and attempt to manipulate and control are created by them. The *entities* manifest in those phenomena are not their creation. Never should we infer from the fact that our practices are necessary for access to scientific entities to the conclusion that those entities are *constituted* by our (linguistic) practices.

What made cognitive relativism such a life issue in the debates from say the time of the 1960s is that there are well-founded philosophical grounds to be skeptical about (scientific) realism. When it comes to realism, relativists are skeptics about the claim that our theories can tell the truth about this independent ontological realm. What they reject is the idea "that reality has an idiom in which it prefers to be described, that its very nature demands we talk about it without fuss – a spade is a spade, a rose is a rose – on pain of illusion, trumpery, and self-bewitchment" (Geertz). Our theories aren't in any obvious way about the ontology of the world; at best we develop a discourse ontology to talk about it.

The recalcitrance of the 'world out there' in no way explains why a particular theory is held at one time or another. At best it explains why the history of knowledge is a graveyard of rejected theories. Formulated in a more general way, the relativist claim that what philosophers take as explanatory notions for why a specific theory is held at one time or another, such as logic, methodology, rationality, are taken on their own or taken collectively, is insufficient to explain the content of a (scientific) theory. Numerous case studies have made clear that there is no such thing as a single conceptualization of let's say the idea of methodology that can account for the many uses that is being made of it over time. Feyerabend's famous and notorious remark 'anything goes' needs to be read as a *reductio ad absurdum* of his opponents who put forward a view of science based on a restricted set of methodological rules and principles. His point is that if you want a general rule that is historically adequate, i.e., fits all instances of historical development, you should go for 'anything goes.' Please notice the conditional formulation here. He is not offering this as his own constructive position, although of course his diagnoses of the ills of his opponent's views do influence his alternative of methodological pluralism: there is no single rationality, no unique way of attaining knowledge, and no single body of truth to be thereby attained.

Relativism and Its Key Concept: Incommensurability

An obvious response to this line of argument is that scientific knowledge is generated by a combination of different kinds of rules, principles, or practices, be they methodological or epistemological as well as ontological assumptions. True as that may be, this doesn't in any way reign in the room relativists claim for their own. Quite the opposite, it enhances their position. They claim that with the demise of the logical-empiricist view of knowledge, the idea that methodological rules are independent from say epistemological ones or ontological assumptions doesn't hold any longer. Since this argument leads directly to what is the key central claim of relativism – different theories, paradigms, research programs, are incommensurable – it is best to explain what the idea behind incommensurability is before proceeding with my exposition.

Suppose you're living in England in 1845 and interested in 'natives.' What would you start reading? In all likelihood you would end up with a book called *The Natural History of Man* by J.C. Pritchard MD, FRS (1786–1848) and just on the market in an enlarged second edition. If lucky, you would be able to find his *Researches into the Physical History of Man* written in 1813 as well. In case you have never heard of Pritchard – founding father of ethnology and the notion of 'diminished responsibility' can be traced back to him – his ideas are used as the main conceptual tool to present the many different peoples that make up the empire to the visitors of that "*realisation of the unity of mankind*" (Albert, Prince Consort): the great exhibition of 1851 at Crystal Place. Fast forward to 1865. Which book would you pick up? Most likely *Ancient Law*, by H.J.S. Maine (1822–88).

Significant about the change from Pritchard to Maine is that for Pritchard the central question is the challenge set by the emergence of comparative anatomy and its tendency toward a polygenist view of mankind. Dark-skinned people were taken as a separate species of mankind, and so were the Indians, etc. This runs counter to the monogenist view as presented in the bible and very well defended by the Society of Friends member Pritchard. Pritchard's main research question is a physical one.

But Maine's research question is totally different. He is interested in the social organization of savages. Apart from how this change from physical anthropology to social anthropology came about, and why it happened at the time it did – in France the change only comes into full effect after World War I – the question does present itself how best to pinpoint in any reasonable detail what is going on in this change.

We have two approaches: one physical and one social. Incommensurability is at play here and refers to specific types of difference between the two approaches. (Please note that incommensurability doesn't mean two approaches can't be compared; the point of its introduction is to clarify what is involved when we do compare alternative and rival approaches.) Prima facie each approach invokes different kind of properties and regularities, the notions of explanatory adequacy differ, and in a sense both approaches, because there doesn't seem to be much common ground between them, are in a deep sense dealing with a different problem. That's because the two approaches start from irreconcilable initial assumptions yielding irreconcilable practices of explanation.

With this in hand it is easy to understand what incommensurability is about. Incommensurability points to differences in, among other things, standards of explanatory adequacy, object domain, etc. What makes rival paradigms incommensurable is not their mere difference but the fact that these differences are (1) irreconcilable and (2) incorporated into the practices each paradigm sets for itself. Incommensurability can exist between two successive paradigms as well as between two or more competing paradigms. For the latter, think about the disagreements between behaviorists, cognitive psychologists, and psycho-analyses.

Let this suffice as an explanation of the concept of incommensurability. What are the implications of the fact that there are commensurable paradigms? Philosophically the most disturbing one is that no theory or paradigm can be privileged over another. If one wants to familiarize oneself with a paradigm one has to come to terms with an inextricable mixture of assumptions, notions, working practices, axiological orientations, etc. The implications of this are far reaching. Arguments to justify a paradigm tend to become close to circular arguments. There is no obvious way to deny that there is an element of self-vindication when a paradigm is justified in terms of its being able to account for empirical results. The key objection to relativism can now be formulated in a concise way: what to do with the Caprice problem?

Suppose Caprice decides to form a community of self-appointed experts on say climate change. Suppose that having gone over all the evidence they reject the anthropogenic thesis of climate change. Is there any (independent) argument available to rule out the social monad created by Caprice as unscientific? Is there any argument to prevent science as being portrayed as any activity of a group of self-validating experts? The sting of the Caprice problem is that there is no standard higher than the assent of the relevant community. If there is such an argument it in all likelihood is tied to the independent causal effectiveness of the 'world out there,' for example, 'long term proven reliability.'

Take, for example, chicken sexing, a manual skill that involves a lot of tacit knowledge. A company that depends for its economic survival on this knowledge needs to get sex determination to be as close as possible to a 100% right. (As it turns out, 2 out of a 100 are wrong.) Clearly the long-term success of the business is an independent test of the chicken-sexing process. If there is a clear and independent pragmatic criterion available, then obviously the answer is affirmative and one could conclude the case. But does this apply to the case of the climate deniers? For sure, of all the scientific papers published on climate change less than a quarter of one percent challenge the anthropogenic thesis of climate change. Of course this fact need not have much impact on the Caprice group – nor that the scientific consensus on this research is that it is of dubious quality.

What the Caprice example brings into to the fray is the thorny issue "What does it take to convince this group that climate change is indeed happening?" and "How long may it take to arrive at this conclusion?" The crux in this example is that if by 2050 all the evidence is finally deemed to be conclusive, it probably is too late to do anything about it. Acting now however involves making fundamental adjustments in our way of living and for that reason is politically a highly sensitive conclusion.

One way of tackling the Caprice problem is in terms of the political constitution of science. Are there paramount values that make up the science game? Its silly to say there are none. A sensible approach seems to be (1) to allow for a certain amount of variation over time of these values and (2) to allow for some variance of emphasis between different domains of knowledge – experimentation is sensible for certain domains in psychology but not for anthropology. If this is done an affirmative answer is defensible. Traditionally, what is described as central to scientific endeavors is that researchers develop hypotheses, systematically test them through data collection and analysis, and produce publishable results while archiving the data for replication. Triangulation – the use of two or more different methodological approaches to study the same phenomenon; the aim is to make sure you get independent corroboration of the data and/or method you're investigation – needs to be added here. Philosophers traditionally have talked about criteria a theory has to live up to in terms of values like accuracy, consistency, scope, simplicity, and fruitfulness. Given the impossibility to solve the Popperian demarcation problem, it is an illusion to think that however we made up this 'political constitution of science,' this will forever separate real science form the crypto- and proto-science. As case studies have shown, those trying to show that parapsychology is a truly scientific endeavor apply these paramount values much stricter than is being done in standard science. This is all to no avail; they are still not included in mainstream science. However, if we look at the sometimes-heated discussion about the scientific states of psychoanalysis, the striking point is not that those paramount values do not yield a unanimous outcome – that is more or less to be expected, experts have a habit of disagreeing among themselves over nearly everything – but the very limited number of values that are invoked at all. In short that it makes sense to take a restricted set of paramount values as the core of the political constitution science.

The suggestion to be entertained here is that cognitive relativism is in the end a much less radical thesis than claimed

by its critics. As with any social practice, the freedom there is a constrained one.

People who are usually called 'relativists' are those who say that the grounds for choosing between incommensurable opinions are less algorithmic than had been thought, not that they are made in complete freedom nor that they are made without justifications. What relativists argue is that scientific rationality in action amounts to an informed opinion, derived from a particular point of view on the issue in question, a reasoned judgment. Judgment, here, is defined as a temporary and fallible verdict that articulates the assessment of the available and relevant information. A judgment is made and informed by the political constitution of science.

Relativists Are (Social) Constructivists

Relativists are philosophically best classified as post-empiricist: they all claim the logical empiricist view is found to be wanting. It's because of the flaws in the philosophical elucidation of knowledge practices that the proponents of cognitive relativism were able to claim the integrity of an intellectual space of their own. No longer did they have to labor under the assumption that a sociological understanding of knowledge was only possible if scientific knowledge was excluded. Even the founding fathers of the sociology of knowledge, such as Weber, Scheler, and Mannheim, at the beginning of twentieth century, subscribed to that view. For relativists the gaps in the philosophical understanding of knowledge had to be plucked by means of sociological mechanisms and principles like interest and/or tradition.

One obvious drawback of this line of reasoning is that the sociological argument is a kind of 'philosophy of gaps' argument: only at those places where the traditional philosophy of science falls short of its explanatory power is there room for a sociological argument. Up to a point this criticism is correct. The sharper criticism is that the sociological theory that the relativists propose is very much of a short-range nature. It deals mainly with the local squabbles within a highly specialist community.

The scientists themselves may feel they are contributing to the solution of the bigger problems in society but their wrangling over the correct interpretation of nature is with other specialist. It is this wrangling or negotiation that is at the core of the sociological analyses of science. Having arrived at this point, a distinction needs to be made between (social) constructionism and constructivism. (If everything is subject to a social process of negotiation, adding the word *social* in one's description of the constructionism loses much of its edge, so the notion of 'social' might as well be left out of it altogether.)

Constructionism aims at showing how and why particular concepts like, for example, 'the noble savage,' or 'religion,' came into being. The idea is to show how it is the outcome of a historical process and the stress is on the contingent social historical determinants of that process. Implication of that argument is that X need not have existed, or need not be at all like it is today. In a way constructionism is trivially true, but let no one lose sight of what the strength of the position is: it asks important questions such as who determines what the problem is and who determines what the solution is? Is the current economic crisis like the one in the 1980s? In which case a monetarist stance is the solution, i.e., get the deficit under control by slashing government spending and deflating wages and house prices. Or is it a debt crisis? In which case classical austerity measures are only going to exacerbate the financial hole governments and the public are in, and more emphasis on short-term measures to stimulate the economy, via increasing the debt ratio, and getting it back on the path to growth seem to be preferable. Obviously the answer is hard fought over and is a highly charged political affair.

Constructionism explores the essential contestability of any social ontology and as such needs to be sharply distinguished from constructivism, which holds that the only reality with which an inquirer can have any cognitive commerce is reality as he constructs it to be: we only know X when we can construct X. This is the tradition of the maker's conception of knowledge that received its full philosophical articulation in Vico's *verum ipsum factum* (the truth is what is made). The attractiveness of the constructivist position is that it in a direct manner gets rid of the evidence-transcendent meaning surplus of absolutist notions like truth, rationality, and reality.

Constructivism sidesteps the skepticism by arguing that knowledge is not 'grounded' in experiences but in non-verbalized and hence noncognitive, routines, and actions. Practice of course directly brings with it the suggestion of routine and lack of questioning. Learning it requires a familiarization with the ways of manipulating the resources that are taken for granted. Again we arrive at the point that what is central to a relativistic understanding of knowledge is that the locus of knowledge is the community of expert practitioners.

The West versus the Rest

'Relative to our culture' is equivocal: culture can either refer to expert group or civilization. When you train as anthropologist you have to pass a series of the tests set by the community of experts in that field: write an ethnography based on your fieldwork experience among a particular group of people, say beekeepers, in which you provide thick description of closely studied phenomenon. You describe their way of living, their engagement with the bees, the skills required etc. If you train as a psychologist you learn to do experiments, how to assess the data and test different hypotheses via various complex statistical technics, etc. Relativism on the professional level means that every expert group sets its own requirements to become a qualified (licensed) member of it. In some cases, the medical profession for example, there is a legal framework in place for this.

Relativism on civilizational level is different: it reflects the prestige science as a knowledge-generating activity has. Relative to 'our culture' in the West means relative to what 'science' – or given that it comprises of many different knowledge domains – relative to the 'sciences' may be the more appropriate way of putting it. This reflects that in the West science is the only legitimate knowledge-generating activity, that science is reason's exemplar. Substitute Islam for the West and the picture radically emerges. Seyed Attas, in his book *Islam and Secularism*,

has a chapter called 'Dewesternization of Knowledge,' and the opening reads as follows:

> Many challenges have arisen in the midst of man's confusion throughout the ages, but none perhaps more serious and destructive to man than today's challenge posed by western civilization. (…) the greatest challenge that has surreptitiously arisen in our age is the challenge of knowledge, indeed, not as against ignorance; but as knowledge as conceived and disseminated throughout the world by Western civilisation; knowledge whose nature has become problematic because it has lost its true purpose due to being unjust conceived, and has been brought about the chaos in man's; life instead of, and rather than, peace and justice; knowledge which pretends to be real but which is productive of confusion and scepticism, which has elevated doubt and conjecture to the 'scientific' rank in methodology and which regards doubt as an eminently valid epistemological tool in the pursuit of truth; knowledge which has, for the first time in history, brought chaos to the Three Kingdoms of Nature, the animal, vegetable and mineral. (…) What is formulated and disseminated is knowledge infused with the character and personality of that civilisation – knowledge presented and conveyed as knowledge in that guise so subtly fused together with the real so that others take it unawares in *toto* to be the real knowledge *per se*. (Emphasis in the original.)

This is, indeed, a pronounced, elegant, and powerful critique of Western science. To understand the reasoning behind it, it needs to be contextualized.

The hostility of an Islamic traditionalist like al-Ghazzali (1058–1111) or his modern-day equivalent Qutb (1906–66) against knowledge that is acquired through the application of reason and logic is easy to understand if we start with the word الإسلام (Islam), which means (voluntary) submission to Allah. To be a follower of Allah implies accepting القرآن (Qur'an) as Allah's direct word, the willingness to live in accordance with the Qur'anic law, and accepting the shari'ah as the sole source of regulating and legislating all aspects of human live. This obedience to Allah is embodied in the Qur'anic verse "I created jinn and mankind only that they might worship Me" (51:56). The education that the Prophet Mohamed received through the Qur'an is from an Islamic perspective the ideal model to emulate. The Prophet is the most perfect example of *al-insan al kamil* (The Perfect Man – perfect because of the near complete realization of the Divine in worldly realities) and the function of education is to strive to produce men and women resembling him (the Prophet) as nearly as possible. A comprehensive and integrated approach to education in Islam strives to produce a balanced growth of the total personality through training man's spirit, intellect, rational self, feelings, and bodily senses such that faith is infused into the whole personality. The aim of Islamic educational theory is the actualization and perfection of all dimensions of the human being. But a balanced growth of the human character requires that both the heart (*qalb*) as the seat of the spirit and the intellect (*ᶜagl*) should receive equal attention.

The glorious Qur'an is the foundation of Islamic education; it is an immutable source of fundamental tenets of Islam, of its principles, ethics, and culture. The élan of the Islam is moral. The crucial point is that the idea of Islam, of submission, has quite radical implications for epistemology and rationality. Any source of authority is to be grounded in Allah. The implication of "Verily with God is full knowledge and He is acquainted (with all things)" (31:34) is that the Qur'an contains all of knowledge in principle and stands at the apex of modes and sources of knowledge.

Because it provides the essential foundation for all forms of knowledge, revelatory knowledge is the most elevated form of knowledge. The insistence on this divine sovereignty implies a rebuttal of any rationalist theory in which reason alone becomes both method and justification of human knowledge. Such a rationalist theory of knowledge is objectionable because it represents human encroachment on the realm of divine authority and is usurpation of Allah's rightful authority and yields a corrupted concept of the world:

> To favour reason at the expense of spirituality hampers balanced growth. Exclusive training of the intellect, for example, is inadequate in developing and refraining elements of love kindness, compassion and selflessness, which have an altogether spiritual ambiance and can only be appealed to by processes of spiritual training. Separating the spiritual development of the human being from the ration, temporal aspects of the same person, (…) is the main cause for the disintegration of the human personality. (Cook, 'Islamic versus Western Conceptions of Education': p. 346.)

To ascertain truth by complete reliance on reason alone is restrictive since both spiritual and temporal reality are two sides of the same sphere. Indeed, the highest form of knowledge is the perception of God (*idrak*), which cannot be realized in any other way than through faith (*iman*).

An important point here is that there is no room for legitimacy of whatever kind to knowledge claims based upon human reason alone. What is denied is that the world is ascertainable through purely rationalist method. This of course does not mean no knowledge could be produced that way, but only that it is without legitimacy. There is no room for an epistemology that assumes that truth about the world can be reached solely through the human faculties. For that to be the case any knowledge endeavor most be premised upon divine transcendental truths, most accept that knowledge starts by accepting the undiluted supremacy of divine authority and the eternal truths that are implied by this acceptance. The dominance of rote learning in the Islamic civilization signals the restricted source of the legitimacy that is allotted to human reasoning, and it reflects that legitimacy is not placed with man's inherent ratiocinating capacities. (It is this line of thinking that is behind the naming of Boko Haram, a radical Islamist group in Nigeria. In Hausa '*Boko Haram*' means 'Western education is sinful,' from the Hausa word *Boko*, western education, and the Arabic word *haram*, sin, literally forbidden.)

What this example shows is two things. Science as reason's example is a culturally specific idea that presented itself in the West, but there is no reason to assume that it is a viable option elsewhere. Secondly, attempts to critique relativism because it naturalizes reason, i.e., all that is left of notions of truth, rationality, and knowledge is a nonnormative *in situ* description, begs the question. Of course any human being has the capacity to reason, and without a doubt in any kind of reasoning there is a critical or transcendent function that can be used to criticize existing norms and practices. The question at

issue is what is the legitimacy of the intellectualistic knowledge produced in this way? The Islamic case makes clear that it is relative to the tradition one is part of.

Relativism: Philosophical Aspects

Maria Baghramian, University College Dublin, Dublin, Ireland

Published by Elsevier Ltd.

Abstract

Relativism starts with the premise that standards of truth, rationality, and ethical right and wrong vary greatly, and there are no universal criteria for adjudicating between them. Faced with intractable differences and disagreements the relativist argues that what is true or right can be determined only within (variable) contexts of assessment and therefore there could be more than one standard of correctness. Several interrelated doctrines are subsumed under the single heading of 'relativism': cognitive, conceptual, ethical, and semantic relativisms are some main subdivisions. The most common criticism is the charge of incoherence, for if 'all is relative' then so is relativism. Despite frequent attacks, relativism retains its appeal because it captures an essential insight about the unavailability of a univocal solution to most human problems.

Definition

Relativism is the view that cognitive, moral, or aesthetic norms vary with and are dependent on the specific social, conceptual, or linguistic contexts that underpin them, and consequently a neutral standpoint for evaluating such norms is not available. Relativists usually rely on the observation that opinions and judgments on matters of fact and value vary greatly between individuals, societies, and historical epochs and that there are no universal criteria for deciding between them. In effect, relativism can be seen as a strategy for overcoming intractable disagreements on matters where adjudication between strongly held views seems impossible. Faced with incompatible beliefs and norms, held with equal conviction, and in the absence of an overarching or universal justificatory scheme, we are pushed to the two extremes of skepticism (the Pyrrhonian option) or relativism (the Protagorean option). To put it slightly differently, presented with the contested pair of beliefs P and its negation not P, the skeptic abandons all claims to knowledge, while the relativist accepts the truth of both by making truth dependent on a hidden parameter such as culture, a conceptual scheme, or semantic context. In addition, relativists assume that different perspectives cannot converge, and in this they stand in opposition to universalist and absolutist aspirations to truth and knowledge.

Historical Background

The earliest documented source of relativism in the Western intellectual tradition is Plato's account of the Sophist philosopher Protagoras and his famous dictum, "Man is the measure of all things; of the things that are, that they are; and of the things that are not, that they are not" (Plato, 1961). The trigger for relativistic tendencies in ancient Greece, as in later times, was the increased contact between people of different cultures, customs, and beliefs, and the realization that other societies arrange their social and ethical lives in radically different ways. Relativism was subsumed under skepticism by the Pyrrhonian skeptics who in turn influenced Michel De Montaigne (1533–92), a key figure in the emergence of modern philosophy. Contemporary relativists, however, are influenced by the perspectivism of Friedrich Nietzsche (1844–1900) and the historicism of Wilhelm Dilthey (1833–1911).

According to Nietzsche, all claims of knowledge are representations of reality only from a certain standpoint. Reports of so-called 'facts' are interpretations that could always be supplemented or replaced by other interpretations. Language is not a means of describing what there is, but rather, it imposes its own interpretation on our thinking. Thus, the very idea of truth and reality is called into question by Nietzsche. Whether Nietzsche's perspectivism should be equated with relativism is open to debate, but his writings have become a source of inspiration for postmodernist and relativist thinkers such as Michel Foucault, Jacques Derrida, and Jean François Lyotard. Like Nietzsche, postmodernism, a dominant theoretical approach in literary theory, sociology, social anthropology, cultural studies, and feminist theories since the 1980s, scorns the quest for universal cognitive and moral values as a manifestation of the 'will to power.' Postmodernism, with its attendant relativistic approach on the other hand, is presented as an ally in the fight for emancipation from tyrannies of all sorts, including the hegemonic tyranny of science with its universalist aspirations.

Contemporary relativism has also been shaped by Wilhelm Dilthey's view that each nation can be seen as a self-contained unit with its own conception of reality and system of values. Different historical periods, Dilthey maintains, produce different norms and values, each of which is taken to be unconditional or universal. We cannot gain a correct understanding of social and intellectual conditions if we do not understand or take into account the inevitable historicity of all thought. Dilthey's views have been particularly influential among the advocates of cultural relativism (see Section Cultural Relativism).

Motivations

The contemporary appeal of relativism arises out of certain features of our experiences of the world, as well as a number of intellectual currents.

The Situatedness of All Judgments

Relativists frequently justify their position by pointing out the many ways in which our judgments and claims to knowledge are bound by particular situations and contexts. Many of our

assertions refer to events that happen at a particular time and place, and are experienced by a particular individual. Such assertions seem to be true only at the time, place, or circumstances of their utterance, and in that sense are relative to these parameters. Moreover, our beliefs, it is claimed, are always from a point of view, a perspective. We cannot step out of our skin, so to speak, and experience reality as it is. A God's-eye view or a view from nowhere is not available to mere humans.

Cultural Diversity

Increasing awareness of the extent of diversity of beliefs, practices, and the customs of different cultures and historical epochs has cast doubt on the universality and objectivity of judgments. Most significantly, the reports by anthropologists about the thinking habits of remote peoples have led to the suggestion that all normative judgments, whether cognitive or ethical, may have only a local validity. Western ethnocentrism and the intellectual legacy of the Enlightenment, it is charged, prevent us from appreciating or even seeing the uniqueness of different cultures and modes of thought.

The Disappearance of Old Certainties

The disappearance of old certainties, both in the religious and scientific arenas, has been instrumental in the increasing prominence of relativism. The questioning of a religiously motivated cosmology, which fixes the position of individuals within an immutable framework, helped to bolster a climate that was conducive to relativistic outlooks. In science, the discovery of the possibility of non-Euclidean geometries in the nineteenth century and Einstein's theory of relativity in the early twentieth century eroded confidence in classical geometry and Newtonian physics. New theories in quantum mechanics and particle physics, Heisenberg's uncertainty principle in particular, are also cited as evidence that universal, absolute laws are rarer than it was once imagined. Darwin's evolutionary theory also eroded the belief in the uniqueness of the human point of view. With the disappearance of the old certainties, the very idea of objectivity came into question.

Varieties of Relativism

Relativism comes in great variety. One way to distinguish between its different forms is to consider the questions:

1. What is it that is being relativized?
2. What is it being relativized to?

These dual questions lead to the following main subdivisions of relativism:

Cultural Relativism

This, probably the most influential form relativism, was a methodological assumption of much of the social sciences from the outset of their emergence as a discipline. Auguste Comte, the founder of the discipline of sociology, is responsible for the catchphrase "all is relative." William Graham Sumner, the first person to give a course titled 'Sociology' in the United States, defended cultural relativism in his book *Folkways* (1906). Social anthropologists who conducted fieldwork among tribal people adopted it as part of their methodology as well as their ethical outlook toward the world. The anthropologist M.J. Herskovits defined cultural relativism as:

> The principle of cultural relativism, briefly stated, is as follows: Judgments are based on experience, and experience is interpreted by each individual in terms of his own enculturation. … Even the facts of the physical world are discerned through the enculturative screen, so that the perception of time, distance, weight, size, and other 'realities' is mediated by the conventions of any given group. (Herskovits, 1960: p. 61)

The doctrine relies on several key assumptions.

1. A methodological assumption to the effect that human behavior and thought should be explained in cultural rather than biological or individualistic psychological terms.
2. The empirical claim that cultures vary greatly in their judgments and values (known as descriptive relativism). Ethnographic data, the claim goes, show that various groups of people hold systems of belief that according to Western standards are false, irrational, and even self-contradictory. The Nuer's belief that twins are birds or the Azande belief in witchcraft and oracles are well-known examples.
3. A philosophical assumption that there is no Archimedean point, or a view from nowhere, to adjudicate between different cultural perspectives.
4. A normative injunction to the effect that we should accept cultures and their practices on their own terms, avoid ethnocentrism, and show tolerance (prescriptive cultural relativism).

Cognitive Relativism

Cognitive relativism is the view that epistemic norms such as truth, rationality, or validity can vary between cultures and conceptual frameworks and that we have no transcultural or framework-transcendent criteria for adjudicating between them. Some main subdivisions of cognitive relativism are relativism about truth (alethic relativism), relativism about rationality and logic, and conceptual relativism.

Relativism about Truth

Relativism about truth, or alethic relativism, is the claim that what is true for one individual or social group may not be true for another and that every effort to adjudicate between context-dependent standards of truth and falsity is bound to be futile. The truth of an assertion, so the claim goes, is relative to the beliefs, attitudes, and other psychological idiosyncrasies of the individuals, or more generally to the conceptual, or cultural, background of the persons making them.

Relativism about truth is the core of all relativistic positions since other subdivisions of cognitive relativism, and even moral relativism, are reducible to it. For instance, relativism about rationality can be expressed in terms of whether there are true (universal) standards of rationality. Relativism about logic may be restated as the question whether logical truths are relative to specific cultures or cognitive schemes or whether

they are in any sense universal. Ethical relativism can be seen as the claim that the truth of ethical judgments is relative to the context or the culture in which these particular judgments are being made. In this sense, alethic relativism is the most general and strongest form of relativism and the target of the most trenchant criticisms of relativism (see 4.1). A semantic version of relativism about truth, known as truth-relativism, has been proposed in recent years and will be discussed in Section Semantic Relativism.

Epistemic Relativism

Epistemic relativism is established through three interconnected claims: (1) beliefs can be justified only relative to systems or frameworks of beliefs; (2) there are many different systems of beliefs – some of which are radically different; and (3) it is impossible to demonstrate (in a noncircular fashion) that our system of beliefs is superior to all others (Williams, 2007). The conclusion drawn is that either we can chauvinistically maintain that our belief system is superior to all or accept the equal legitimacy of all such systems.

Peter Winch's position is an example of this type of relativism. Winch has argued that since standards of rationality in different societies do not always coincide, we should use only contextually and internally given criteria of rationality in our assessment of the systems of belief of other cultures and societies. Winch, who based his arguments in reaction to E.E. Evans-Pritchard's account of the Azande's beliefs in witchcraft and magic and who was greatly influenced by the work of the philosopher Ludwig Wittgenstein, argues that it does not make sense to speak of a universal standard of rationality because what is rational is decided by norms of a given language and the form of life that provides a backdrop to it. We, as outside observers, are therefore not in a position to impute irrationality or illogicality to the Azande or other groups whose practices differ from ours.

Rationality invariably involves the idea of having good reasons, which in turn involves the application of rules of logic and questions of warrant and justification. These components of 'rational thought' have also become targets of relativistic treatment.

Relativism about Logic

Discussions of the Azande belief system, coupled with a strongly relativistic interpretation of Wittgenstein's views, have led Barry Barnes and David Bloor to argue that not only standards of rationality but also laws of logic, often seen as the necessary conditions for rational thought, are defined by and hence are relative to their social context. According to them, the very distinction between valid and invalid modes of argument is relative to the practices prevalent in a given linguistic community or society and cannot in any sense be seen as universal. Bloor argues that there are no culture-transcendent rules of validity and inference. Different societies may have incompatible, but internally coherent, systems of logic, and the norms of logical reasoning are relative to a background of cultural conditioning. According to Bloor, "The Azande have the same psychology as us but radically different institutions. If we relate logic to the psychology of reasoning we shall be inclined to say that they have the same logic; if we relate logic more closely to the institutional framework of thought then we shall incline to the view that the two cultures have different logics" (Bloor, 1976: pp. 129–130).

Relativism about Justification and Warrant

A rational person is expected to have justification for her views and warrant for her beliefs. The relativist argues that the legitimacy of a justificatory system and the perceived strength of epistemic warrant are only decided locally. Richard Rorty, who has been accused of relativism, by among others Hilary Putnam and Paul Boghossian, has made the influential claim that "there is nothing to be said about either truth or rationality apart from descriptions of the familiar procedures of justification which a given society – ours – uses in one or another area of inquiry" (Rorty, 1991: p. 23). The belief in the necessarily parochial scope of any justification or reason we may offer is a hallmark of relativistic thinking.

Conceptual or Ontological Relativism

Conceptual or ontological relativism is motivated by philosophical considerations about the relationship between human thought and the world rather than mere cultural and historical differences. The roots of conceptual relativism rest with Immanuel Kant's (1724–1804) distinction between the data of our sense experiences and the principles of organization or the categories we use to organize them. Kant, unlike the relativist, believed that all thinkers necessarily apply the same categories or conceptual schemes to the undifferentiated flow of their experiences. However, once the distinction between a conceptual scheme and its content was introduced, it was easy to accept that there could be more than one system or scheme of organization – thus the idea of conceptual relativism was born. Conceptual relativists argue that, at least in principle, there is a multiplicity of ways of carving up the world, and the so-called 'facts' are delineated by human interests and modes of thought rather than the impersonal hand of nature. One of the most influential versions of conceptual relativism in the twentieth century was proposed by W.V.O. Quine, according to whom, to be able to talk about the world and to cope with our stream of sensory experience, we must impose on it a conceptual or linguistic scheme or theory. However, given the underdetermination of theory by available data, it is possible to envisage a plurality of conceptual or theoretical frameworks, all of which explain and predict our sensory experiences equally well. There are no determinate facts to enable us to choose between these varying frameworks; hence what Quine has called 'ontological relativity' ensues.

The influence of Quine's views is widespread. We can, in particular, see its impact on the writings of Nelson Goodman and Hilary Putnam who proposed very sophisticated forms of conceptual relativism. Putnam, for instance, has denied that there is a fact of the matter as to what counts as an object outside the standards set by a conceptual scheme. One and the same situation, according to Putnam, can be described "as involving entirely different numbers and kinds of objects" (1992: p. 122), and we do not have an account of which of these is the right description external to and independent of all conceptual schemes. It is important to note that most conceptual relativists, Quine and Putnam in particular, wish

to distance themselves from cultural relativism, which they think is fundamentally incoherent. Their brand of relativism is based on their theories of meaning and content rather than the purported differences between cultural traditions.

Relativism about Science

Conceptual relativism also informed the work of Thomas Kuhn and Paul Feyerabend, who emphasized the formative role of different paradigms and models of reasoning at various periods in the history of science. In their different ways, they have argued that scientific theories, developed within differing paradigms, are incommensurable or incomparable. Each paradigm acts as a unique and untranslatable language or conceptual framework, and since rival paradigms do not have access to a common criterion for adjudication, they remain self-contained and beyond the critical reach of their presumed rivals. Kuhn's and Feyerabend's writings, in turn, had a formative role on the Strong Programme of Sociology of Science of Barnes and Bloor (see 3.2.3), and the so-called 'Science Studies.' Conceptual relativism also informed the work of Thomas Kuhn and Paul Feyerabend, who emphasized the formative role of different paradigms and models of reasoning at various periods in the history of science. In their different ways, they have argued that scientific theories, developed within differing paradigms, are incommensurable or incomparable. Each paradigm acts as a unique and untranslatable language or conceptual framework, and since rival paradigms do not have access to a common criterion for adjudication, they remain self-contained and beyond the critical reach of their presumed rivals. Kuhn's and Feyerabend's writings, in turn, had a formative role on the Strong Programme of Sociology of Science of Barnes and Bloor (see 3.2.3), as well as on Bruno Latour and other social constructionists. According to the social constructionists, scientific facts, and even reality – or 'the world' with its objects, properties, and categories – are not simply out there to be discovered by scientists, rather they are constructed via communal norm-governed processes and practices such as negotiations, interpretations, and manipulation of data (as well as accidental and opportunistic developments). Scientific discoveries and theoretical knowledge are the products of socially sanctioned norms and practices and are guided by projects that are of cultural, economic, or political importance. As Latour and Woolgar put it, "Our point is that 'out-there-ness' is the consequence of scientific work rather than the cause" (1986: p. 180). The high point of the debate on relativism about science, or the 'Science Wars,' was the publication of the infamous 'Sokal Hoax.' In 1996, the postmodernist journal *Social Text* published an article by the physicist Alan Sokal where he mimicked relativist and postmodernist objections to the objectivity of science. Sokal then went on to confess that his paper was full of non sequiturs and was but a sham. The ensuing 'science wars' colored much of the discussions of relativism at the turn of the twenty-first century. The debates are still continuing, but they have lost their 'war-like' tone (see Ashman and Baringer, 2000).

Moral Relativism

Moral or ethical relativism is simultaneously the most influential and the most reviled of the relativistic doctrines. Supporters see it as a harbinger of tolerance, open mindedness, and antiauthoritarianism. Detractors, including Pope Emeritus Benedict XVI, think it undermines the very possibility of ethics and is a sign of either confused thinking or moral turpitude. Briefly stated, moral relativism is the view that right and wrong, good and bad are relative to and vary with individual or cultural perspectives and frameworks. The first position, where the individual's preferences and judgmental framework provide the context of relativization is known as subjectivism, while the latter, where cultural and social frameworks are the context of relativization, is moral relativism proper. Moral relativism can and often is embraced independently of cognitive relativism, for ethical relativists may agree that convergence between diverse worldviews and theoretical frameworks is possible in the natural sciences but deny that this is the case for values. There is a fundamental cleavage between scientific and moral enquiries, they argue, because moral precepts and judgments, unlike the posits of science, are not part of the natural furniture of the universe; they are man-made and would not exist independently of human actions, beliefs, and customs.

Moral inquiry is concerned with how life should be lived and how human beings should behave toward each other and their world. Moral relativists start from the premise that moral values are grounded on societal conventions, historical conditions, metaphysical beliefs, etc., which vary from one society or social grouping to another and argue that there are no neutral standards available to us for adjudicating between such competing claims. The truth or falsity, the appropriateness or inappropriateness of ethical beliefs, are relative to their socio-historical backgrounds, and moral beliefs cannot be assessed independently of their social framework. In that sense, it could be seen as a subspecies of cultural relativism (see Section Cultural Relativism).

Moral relativism is usually subdivided into descriptive, ethical and metaethical varieties. Descriptive moral relativism is an empirical doctrine based on observation of diversity in moral values across different societies and historic epochs. There is widespread disagreement among individuals and cultures on issues ranging from capital punishment to abortion, from human rights to animal rights. Descriptive relativists go so far as to accept that there may be broad similarities in the core beliefs of different societies, for instance, injunctions against the killing of innocents, but argue that such shared values are given very different and even incompatible interpretations by different cultures.

Ethical relativism is a normative position, informed by descriptive moral relativism, claiming that "it is wrong to pass judgment on those who have substantially different values, or to try to make them conform to one's values, for the reason that their values are as valid as one's own" (Wong, 1993: p. 442). In this, ethical relativism has much in common with cultural relativism and is similarly associated with tolerance and open mindedness (see Section Cultural Relativism). It is sometimes argued that ethical relativism is itself a normative doctrine insofar as it prohibits interference with the ways of life and moral practices of other cultures. But this degree of tolerance can also lead to moral indifference and even nihilism. A relativist does not have the certitude to condemn genocide, torture, or child abuse, for example, so long as such actions are seen as

part of the fabric of the social life of some cultures and peoples. Furthermore, if ethical relativism is true, then even tolerance and noninterference could not be seen as universal ethical values and could not be recommended to those who do not already embrace them.

Moral diversity is of course compatible with the possibility that there are right and wrong answers to ethical questions, but finding such answers would depend on having a dependable path toward the discovery of ethical truths or the establishment of a universal framework for arbitrating between incompatible moral claims. Metaethical relativists deny this possibility because they claim that the truth or the justifiability of ethical judgments is internal to the ethical framework agents embrace. Conflicting moral judgments, they argue, can be equally correct or equally justified because what decides their correctness is the moral standard to which their judgment is indexed (see, for instance, Gilbert Harman, 2010; Dreier, 2006).

Semantic Relativism

Semantic relativism, also known as 'new relativism' or 'truth-relativism,' has arisen out of work in the philosophy of language in the analytic tradition. Semantic relativism is the view that some statements can be characterized as true only relative to a context of assessment. John MacFarlane, a champion of this new approach, claims that the *truth*-conditions of utterances for a certain class of statements, e.g., disputes about taste and values, future contingent propositions, and attributions of knowledge, may be appropriately treated as true relative not just to their context of use but also to the *contexts of assessment*. A statement can be true relative to one 'context of assessment' and false relative to another (MacFarlane, 2005, 2007). This sort of relativism is seen as useful for explaining away what has become known, after Max Kölbel, as instances of faultless disagreement. Kölbel (2004) motivates truth-relativism by finding faultless disagreements in contexts that lack objectivity but which are nevertheless truth-apt. A disagreement is faultless where one person asserts a proposition p and the other denies or disputes it and asserts negation or not p (the condition of disagreement), but neither party could be said to have made a mistake in their assertions (the condition of faultlessness). In such circumstances, we have to say that both parties are correct, and therefore both their beliefs p and not p must be true. The truth-relativists' way to deal with this scenario is to say that each belief is true relative to a perspective. To take an example, in a situation where A asserts that "rhubarb pies are delicious" and B disputes this by asserting the contrary, i.e., "Rhubarb pie is not delicious," both A and B could be thought of as saying something true if truth is relativized to a taste parameter. A is asserting something true with respect to her standard of taste and false relative to B's (MacFarlane, 2007; Wright, 2008). One strength of truth-relativism is that it retains our intuition that some judgments are subjective and yet open to genuine disagreement, in so far as they have shared content. The position, however, has come under attack, among other reasons, for its failure to respect deep-seated intuition about truth as a norm of assertion (Greenough, 2010; Baghramian and Hamilton, 2011). The position has also come under attack by those with equally deep-seated intuitions that truth is fundamentally a monadic and nonrelative property of propositions (e.g., Cappelen and Hawthorne, 2009).

Arguments against Relativism

Critics of relativism have found the doctrine incoherent. The charge of incoherence has been leveled in different ways, the most common of which is the charge of inconsistency. The argument goes back to Plato whose paradigmatic argument against the relativist Protagoras amounted to the claim that relativism, at least in its stronger global form of relativism about truth, is either inconsistent or incoherent because of the dubious status of the claim that "truth is relative." If "truth is relative" is itself true unconditionally, it is argued, then there is at least one truth that is not relative, and hence relativism is not true. If, on the other hand, "truth is relative" is true only relative to the relativist's framework, then the relativist's advocacy of his position is devoid of significance. To avoid inconsistency a relativist should accept that "truth is relative" is itself only relatively true, i.e., true only for people who endorse it, but then she or he would not be in a position to convince an antirelativist of the legitimacy of the claim. The relativist is condemned to silence.

Variants of the charge of incoherence have been proposed. Hilary Putnam, for instance, has argued that relativism is ultimately incoherent because it cannot distinguish between being right and thinking that one is right. And without such a distinction, thinking and speaking become impossible (Putnam, 1981). Paul Boghossian (2006a,b), on the other hand, has focused largely on social constructionist arguments for epistemic relativism. He argues that relativism fails because of the incoherence of its claim of "equal validity," the claim that "There are many radically different, yet 'equally valid' ways of knowing the world, with science being just one of them" (Boghossian, 2006a,b: p. 2). To accept the doctrine of "equal validity," Boghossian argues, is to give up on all our pretheoretic ground level intuitions on truth, knowledge, and justification.

A different version of the accusation of incoherence is directed at the intelligibility of the relativist's claim that one and the same statement may be true for one linguistic community and false for another. Donald Davidson, the main advocate of this position, argues that all types of relativism rely on the assumption that there can be radically divergent conceptual schemes or systems of belief. But in order to be in a position to make the claim that a system of belief or cognitive scheme diverges from ours in a significant manner, we first need to identify such a scheme and the beliefs that result from it. But in order to identify something as a belief, Davidson argues, we must be able to interpret it (or translate the sentence expressing that belief into our language). To translate a sentence or to assign meaning to it, Davidson maintains, we will have to regard that sentence, or the belief system underpinning it, as true or in agreement with us. A correct understanding of the beliefs and other propositional attitudes of a person, Davidson maintains, leads to the conclusion that most of her beliefs must be true. So the relativist cannot get its claim of incommensurability or radical diversity among different belief systems off the ground, because the recognition of such

diversity requires charity in interpretation and presupposes that there are some identifiable commonalities between different languages and belief systems. If this argument is right, then relativism cannot even get started, because arguments for relativism are built on the premise that there are, or can be, fundamental cultural and conceptual differences between human beings.

Relativism has survived 2000 years of attempts to bury it. Its perennial appeal and periodic fashionability are due to its ability to capture and express an essential insight, be it in an exaggerated fashion, about the human condition. The insight that we live in a world of pluralities and do not have access to univocal answers to our diverse problems.

Reliability and Validity Assessment: New Approaches

Duane F Alwin, Pennsylvania State University, University Park, PA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The quality of measurement is considered the *sine qua non* of research in all sciences. In the social sciences, the concern with measurement quality is critical because theoretical constructs are unobserved and often elusive. In order to evaluate the quality of measurement in these fields, it is necessary to, first, develop a model that specifies the linkage between observations and the latent variable(s) of interest; second, to develop a research design that permits the estimation of parameters of such a model; and third, to develop an interpretation of these parameters that is consistent with the concepts of measurement quality. Several traditions exist for the formulation of such models that relate observed to unobserved variables, and the concepts of *reliability* and *validity* are often used to interpret the quality of measurement from such designs. This article discusses the traditional techniques of reliability and validity assessment and briefly presents some new approaches to evaluating the properties of individual measures that are aimed at measuring theoretical constructs of interest.

Introduction

Measurement represents the link between theory and research in all sciences, and the quality of measurement is the linchpin upon which rest our inferences about patterns and processes in the particular subject matter of interest. Almost everyone agrees that the quality of measurement is especially critical in the social and behavioral sciences because variables often lack precise definition and suitable indicators are often lacking. Indeed, it can be argued that without reliable and valid measurement, the contributions of these human sciences would be of little value, given that our inferences depend intimately on having high-quality tools for measurement. The examination of the question of the patterns of measurement error in such social data, often obtained through sample surveys and interview reports, and an evaluation of the quality of such data in general are strongly warranted.

In the social and behavioral sciences, the psychometric concepts of *reliability* and *validity* are essential ingredients to the assessment of data quality, and this is the focus of this article. Validity refers to *what we are measuring*, and it emphasizes the gathering of consensus surrounding 'validity claims' concerning the quality of indicators for assessing essential constructs. Reliability, on the other hand, refers to *how well we are measuring* whatever it is that our indicators specify as constructs of interest. The study of patterns of measurement reliability and validity typically requires repeated measurement (i.e., within-subjects designs), although many things can be learned from between-subjects designs as well. The present article is, however, limited to a focus on assessing reliability and validity using within-subjects measurement, specifying some newer emphases in these matters. I begin, however, with a brief discussion of the concepts of reliability and validity, and the traditional approaches to assessing the quality of measurement.

The Concepts of Reliability and Validity

The following discussion of the concepts of reliability and validity relies in part on a presentation of similar content in Alwin (2009, 2010, 2011). There are two important levels of discourse involved in the conceptualization of reliability and validity – *observed* (or manifest) variables and *unobserved* (or latent) variables. For our purposes, it is important to think of a response to a question in a measurement device to be an 'observed' variable that reflects some 'latent' unobserved variable or construct of interest. We may define the response variable as a random variable (Y), observed in some population of interest, which has a latent counterpart (T), which is also a random variable in the population, and which in part is responsible for the production of the response, i.e., $T \rightarrow Y$. In this sense, we may think of T as a part of (or a component of) Y. There is no necessary identity between the two, however, as we know there are a number of types of measurement errors, which we can represent globally using the notation E, also considered to be a part of Y. In this sense, we can conceptualize Y as having two major parts that contribute to the response, namely, what we are measuring and the errors that impede our ability to do so, i.e., $T \rightarrow Y \leftarrow E$.

Note that while Y is observed, both T and E are unobserved, or latent, variables. This type of formulation allows us to think in terms of two general considerations when examining the variation observed in responses to measures; one is the variation in the underlying phenomenon one is trying to measure, e.g., income or employment status, and the other is the variation contributed by errors of measurement. The consideration of each of these parts – the part concerning the construct one is trying to measure as well as the part concerning measurement errors – is the focus of discussions of reliability and validity.

It is important to note here that our formulation is intended to be very general, allowing for a range of different types of Y and T random variables, Y and T variables that represent discrete categories, as well as Y and T variables that are continuous variables. There are a number of different cases or types of situation involving different types of variables at each level. If Y and T are continuous random variables in a specified population of interest, for example, and if it is assumed that E is random with respect to the latent variable, that is, T and E are uncorrelated determinants of Y, we have the case that is represented by *classical true-score theory* (CTST) (see Lord and Novick, 1968; Alwin, 2007), where the T latent variable is

referred to as a true score and measurement error is simply defined as the difference between the true score and the observed score, i.e., $E = Y - T$ (see Groves, 1989).

In general, there is no constraint on the covariance properties of E and T, although in the CTST case, E is considered to be random, i.e., uncorrelated with T, and this assumption underlies the development of psychometric approaches to estimating reliability. Although we generally find the CTST to be quite valuable in many situations, it has certain limitations, especially when it comes to assessing the reliability and validity of discrete data, e.g., event history data (Belli et al., 2009). For this reason, for purposes of this discussion, we insist on a more general conceptualization, which permits T to be either a set of latent nominal classes, a set of latent ordered classes, or a latent continuous variable, *and* a conceptualization that permits Y to also be a nominal, ordinal, or interval response variable (see Alwin, 2007: pp. 128–130).

Before developing the idea of reliability further, however, it is important to add more complexity, in order to eventually incorporate the concept of reliability into the discussion of validity. Indeed, in addition to reliability, and perhaps of greater interest, is the concept of validity – the extent to which the investigator is measuring the theoretical construct of interest. In a more general sense, measurement validity refers to the extent to which measurement accomplishes the purpose for which it is intended: that is, is one measuring what one intends to measure? Validity is a somewhat more elusive concept than reliability, given the absence of adequate criteria for its evaluation, historically (see AERA/APA/NCME, 1999). Although matters of validity are often thought to be capable of solutions on an abstract level, as with the notion of 'content' or 'face' validity, on an empirical level the issue of validity can only be defined with respect to some criterion that is related to the purpose of measurement, and we often must rely on 'validity claims,' supported by consensus in the scientific community that some X is a valid measure of construct C. When the validity of measurement is at issue, this if often assessed with respect to its correlation with criterion variables, often outside the particular research design, that are linked to records of factual information. In addition, validity is often defined at the level of the construct, that is, the relationship between T (or the latent variable being measured) and the construct of interest, C, i.e., $C \rightarrow T$. Of course, without a direct measure of this 'construct of interest,' one often must fall back on notions of *criterion validity*.

I should note at this point that, although some will mistake it for validity, when traditional psychometric approaches refer to the reliability of measurement *on a conceptual level*, they refer to the closeness of the correlation between Y and T. Thus, when one is dealing with measurements that are reliable, it is assumed that the measurement error part of Y is minimal, and in a 'variance accounting' framework, mostly due to latent or 'true' variation. By contrast, when measures are unreliable, it is because there is a great deal more 'error of measurement' than 'true variation,' that is, much more 'noise' than 'signal,' to use a metaphor from radio telegraphy. Validity, on the other hand, refers to the extent of correlation of between T and C. High reliability is important in part because validity depends on reliability – without highly reliable measures, high validity is impossible. Reliability of measurement is a *sine qua non* of all social science research, and it is readily shown that reliability is a necessary although not sufficient condition for validity (Lord and Novick, 1968; see also Alwin, 2007: pp. 291–292). Specifically, it can be shown that the *criterion validity* of a measure – its correlation with another variable – cannot exceed the reliability of either variable. There is a mathematical proof for this assertion (Alwin, 2007: pp. 291–292), but the logic that underlies the idea is normally accepted without formal proof: if our measures are unreliable, they cannot be trusted to detect patterns and relationships among variables of interest, including the criterion variables one might use to assess validity.

To summarize, for our present purposes we take reliability to refer to the relationship between Y and T (as defined above), whereas validity has to do with the relationship between T and C, that is, between the latent variable being measured and the theoretical construct of interest. When one has a direct record of the variable or a 'gold standard' for this theoretical construct (e.g., employer records of earnings), then one can examine the relationship between T and C. Such designs are relatively rare, but when available, they can be very useful (I return to a brief discussion of these below). Both measures of 'gold standards' and of 'alternative methods' contain measurement error, so such correlations or measures of agreement must always be interpreted in light of reliability of measurement in both variables.

Designs for Assessing Validity and Reliability

Most people agree that there are two basic approaches to dealing with errors of measurement resulting from invalidity and unreliability: (1) one can try to reduce errors in the collection of data, by developing more valid indicators and using more precise and consistent methods of gathering information, and/or (2) one can try to develop models of the processes that produce error. The purpose of the second strategy of modeling error is ultimately to provide feedback on how to reduce errors in data collection, by altering the questionnaire strategies used to collect data, or by abandoning measurement approaches that are fraught with error. The present article focuses solely on the second strategy, namely, question evaluation methods as they are applied in survey research (see Madans et al., 2011).

More than 50 years ago, psychologists Donald Campbell and Donald Fiske (1959) proposed some ideas that continue to express some fundamental principles with respect to assessment of reliability and validity, which are still useful. They argued that both concepts of reliability and of validity require a high level of agreement between measurements – *validity* is supported when there is correspondence between two efforts to measure the same trait through *maximally different* methods; *reliability* is demonstrated when there is agreement between two efforts to assess the same thing using *maximally similar*, or replicate, measures (Campbell and Fiske, 1959: p. 83). Thus, both types of studies involve assessing the correspondence between measurements – studies of reliability focus on the consistency of repeating the measurement using replicate measures, whereas researches on validity are concerned with the correspondence of a given measure to some criterion of interest, taking into account the reliability of either measure.

Articulating these ideas further, Alwin and Krosnick (1991: p. 141) suggested three desiderata for assessing the reliability and validity in the case of survey data:

- First, a model is needed that specifies the linkage between true and observed variables.
- Second, a research design is needed that permits the estimation of parameters of such a model.
- Third, one must be able to offer an interpretation of these parameters that is consistent with the concepts of measurement quality (reliability and validity).

We have already discussed above the general ideas involved in specifying the linkage between true and observed variables. In the following discussion, we focus specifically on the types of research designs that are used to permit the estimation of the parameters of models for reliability and validity assessment.

Validation Studies

Establishing the validity of survey measurement is difficult because within a given survey instrument, there is typically little available information that would establish a criterion for validation. However, there is a well-known genre of research situated under the heading 'record check studies,' which involves the comparison of survey data with information obtained from other record sources. Although rare, such studies can shed light on survey measurement errors; however, as noted earlier, correlations among multiple sources of information are limited by the level of reliability involved in reports from either source (Alwin, 2007: pp. 48–49). As noted earlier, in the psychometric tradition, the concept of validity has mainly to do with the utility of measures with respect to getting at particular theoretical concepts. This concept of validity is difficult to adapt to the case of survey measures, given the absence of well-defined criteria representing the theoretical construct, but several efforts have been made. One important design that has been used for studying validity involves record check studies, where the investigator compares survey reports with a set of record data that may exist for the variables in question in a given population (e.g., Bound et al., 1990; Marquis, 1978).

Another design that has been used in the study of nonfactual content, e.g., attitudes, beliefs, and self-perceptions, involves the application of multitrait-multimethod (MTMM) measurement designs, where the investigator measures multiple concepts using multiple methods of measurement. In recent years, a great deal of attention has been paid to a model originally proposed by Campbell and Fiske (1959), involving the measurement of multiple concepts or 'traits' each measured using multiple methods – hence, the MTMM measurement design (see Alwin, 2007; Saris and Gallhofer, 2007). Using this design, methods have been developed for separating validity and invalidity in survey reports. Its use has been limited to the study of components of variance in measures of attitudes, beliefs, and self-descriptions primarily because there are often not multiple measurement formats for gathering factual data. I return to a discussion of this approach later in this article.

A third type of validation study is what has been referred to as 'gold standard' studies, where an alternative approach to measurement, e.g., an event history calendar, is compared to data gathered on the same people using the method that represents the *gold standard* or the accepted or standard approach to measuring particular content (see, e.g., Belli et al., 2001). All of these qualify under the definition of validity studies, in that they all three are aimed at examining the correspondence between responses to a particular survey question and the 'true' or 'best' indicator of the construct it is intended to measure. All of these validation designs embody the principle articulated by Campbell and Fiske (1959), that the best evidence for validity is the convergence of measurements employing maximally different methods.

Studies of Reliability

With respect to studies of reliability, there are several standard methods of reliability estimation in common use in survey research; however, many of these approaches are inadequate for purposes of dealing with the evaluation of the reliability of specific measures, as will be discussed below. Strategies of reliability estimation for continuous variables are well developed, and we briefly consider these models here – they are discussed in detail elsewhere (see Alwin, 2010). The basic model is derived from a set of definitions about the true score of a fixed person as an expected value of that person's propensity distribution (see Lord and Novick, 1968). The model is typically written as follows:

$$y_{ij} = \tau_{ij} + \varepsilon_{ij}$$

where y_{ij} is an observed score for person i on measure j, τ_{ij} is the true-score counterpart for person i on measure j, and ε_{ij} is measurement error, i.e., the difference between y_{ij} and τ_{ij} for person i on measure j. The assumption of this model is that in a population of persons for whom this model holds, measurement error is random, i.e., ε_{ij} and τ_{ij} are uncorrelated. Stated more formally, $E(\varepsilon_{ij}) = E(\varepsilon_{ij},\tau_{ij}) = 0$. The *reliability of measurement* for y_j in a fixed population, S, is defined as the ratio of the true variance to the observed variance, i.e., $\mathrm{VAR}(\tau_{ij})/\mathrm{VAR}(y_{ij})$, that is, the proportion of the observed variance that is true variance (see Alwin, 2007).

Simple Reliability Models

The classical literature on reliability estimation refers to "the correlation between truly parallel measurements taken in such a way that the person's true score does not change between them is often called the *coefficient of precision*" (Lord and Novick, 1968: p. 134). In this case, the only source contributing to measurement error is the unreliability or imprecision of measurement. The assumption here, as is expected in all such designs, is that "if a measurement were taken twice and if no practice, fatigue, memory, or other factor affected repeated measurements," the correlation between the measures reflects the precision, or reliability, of measurement (Lord and Novick, 1968: p. 134). For two measures, it is possible to relax the assumption of parallel measures and assume only that tau-equivalence holds in order to obtain an estimate of reliability for each of the two measures. Using the above formulation, the reliability of measurement is defined as $\mathrm{COV}(y_1y_2)/\mathrm{VAR}(y_1)$ and $\mathrm{COV}(y_1y_2)/\mathrm{VAR}(y_2)$ in the case of two tau-equivalent

measures, y_j (where $j = 1$ and $j = 2$). The problem, of course, is to be able to design studies that permit the interpretation of this quantity in terms of the parameters of the model.

Internal Consistency Reliability

Cronbach (1951) developed a measure for a composite score of what is often referred to as 'internal consistency reliability' (ICR), which estimates the lower bound of reliability for a set of univocal measures that are tau-equivalent in structure. Let Y symbolize such a linear composite defined as the sum $Y_1 + Y_2 + \cdots Y_g + \cdots + Y_G$, where G is the number of measures. The formula for the ICR (denoted as α) is given as follows:

$$\alpha = \frac{G}{G-1}\left[1 - \frac{\sum_g \mathrm{VAR}(Y_g)}{\mathrm{VAR}(Y)}\right]$$

Jöreskog (1971) reformulated this coefficient for the case of congeneric measures, and Greene and Carmines (1979) generalized all of these models to the general case of linear composites (see also Heise and Bohrnstedt, 1970). It can be shown (although we do not do so here) that this formula is derived from the definition of a classical true-score model of the ratio of the true variance to the observed variance of a composite variable, i.e., VAR(T)/VAR(Y) (see Alwin, 2007: pp. 51–53). Despite their popularity, these ICR models are not technically estimates of reliability in models where univocity does not hold, and given this relatively stringent set of requirements on the design of survey measures, they are often unrealistic for purposes of assessing the reliability in survey measurement. These methods assume the existence of multiple univocal measures of a single underlying variable and independence in the errors of measurement. It is difficult to obtain multiple measures of the same construct in the typical cross-sectional survey, and even when researchers fashion their measures as suitable for the application of psychometric models for reliability estimation, it is difficult to demonstrate that the assumptions required for these models are met (Alwin, 2007).

Common Factor Model Representation of CTST

It is a straightforward exercise to express the basic elements of CTST as a special case of the metric (unstandardized) form of the common factor model and to generalize this model to the specification of K sets of congeneric measures, which makes coefficient α somewhat more comprehensible. Consider the following common factor model:

$$Y = \Lambda T + E$$

where Y is a $(G \times 1)$ vector of observed random variables, T is a $(K \times 1)$ vector of true-score random variables measured by the observed variables, E is a $(G \times 1)$ vector of error scores, and Λ is a $(G \times K)$ matrix of regression coefficients relating true and observed random variables. The covariance matrix among measures under this model can be represented as follows:

$$\Sigma_{YY} = \Lambda\Phi\Lambda' + \Theta^2$$

where Σ_{YY}, Φ, and Θ^2 are covariance matrices for the Y, T, and E vectors defined above, and Λ is the coefficient matrix as defined above.

For purposes of this illustration, we consider all variables to be centered about their means. Here we take the simplest case where $K = 1$, that is, all G variables in Y are measures of T; however, we note that the model can be written for the general case of multiple sets of congeneric measures. In the present case, the model can be represented as follows:

$$\begin{bmatrix} Y_1 \\ Y_2 \\ \vdots \\ Y_G \end{bmatrix} = \begin{bmatrix} \lambda_{1T} \\ \lambda_{2T} \\ \vdots \\ \lambda_{GT} \end{bmatrix} \times [T] + \begin{bmatrix} E_1 \\ E_2 \\ \vdots \\ E_G \end{bmatrix}$$

For G congeneric measures of T, there are $2G$ unknown parameters in this model ($G\lambda_{gT}$ coefficients and G error variances, θ_g^2) with degrees of freedom (df) equal to $0.5G(G+1) - 2G$. In general, this model requires a scale be fixed for T, since it is an unobserved latent random variable. Two options exist for doing this: (1) the diagonal element in Φ can be fixed at some arbitrary value, say 1.0, or (2) one of the λ_{gT} coefficients can be fixed at some arbitrary value, say 1.0. For G measures of T, the tau-equivalent model has $G + 1$ parameters with d$f = 0.5G(G+1) - G + 1$. For a set of G parallel measures, there are two parameters to be estimated, VAR[T] and VAR[E], with d$f = 0.5G(G+1) - 2$. Note that both the tau-equivalent measures and parallel measures form of this model invoke the assumption of tau-equivalence. This is imposed on the model by fixing all λ_{gT} coefficients to unity. In order to identify the tau-equivalent or parallel measures model, observations on two measures, Y_1 and Y_2, are sufficient to identify the model. For the congeneric model, G must be greater than or equal to 3. It should be clear that the congeneric measures model is the most general and least restrictive of these models, and the tau-equivalent and parallel measures models simply involve restrictions on this model.

What has been stated for the model in the above paragraphs can be generalized to any number of G measures of any number of K factors. The only constraint is that the assumptions of the model – univocity and random measurement error – are realistic for the measures and the population from which the data come. Although there is no way of testing whether the model is correct, when the model is overidentified the fit of the model can be evaluated using standard likelihood ratio approaches to hypothesis testing within the confirmatory factor analysis framework. There is, for example, a straightforward test for whether a single factor can account for the covariances among the G measures. Absent such confirming evidence, it is unlikely that a simple true-score model is appropriate, and a different interpretation must be given to the ICR estimate.

To summarize, there are two questionable assumptions of the CTST approach. The first is that the measures are *univocal* measures of a single underlying variable. The second is that the errors of the measures are independent of one another. These assumptions rule out, for example, the operation of memory in the organization of responses to items in a series of questions. Obviously, respondents are fully cognizant of the answers they have given to previous questions, so there is

the possibility that memory operates to an unknown degree to distort the degree of consistency in responses. These assumptions for reliability estimation in cross-sectional studies also rule out the operation of other types of correlated errors, for example, the operation of systematic method factors. Thus, in cross-sectional data it may be impossible to assume that measurement errors in a set of measures are independent, since similar questions are often given in sequence or at least included in the same battery. Given the shortcomings of the ICR approaches, attention has turned to more closely examining the sources of variation at the level of the individual survey question (see Alwin, 2010). Two variants on the basic CTST model have been developed for this purpose, which I briefly summarize in the following: the MTMM measurement design using cross-sectional data and the quasi-simplex approach for longitudinal data.

Reliability Models for Single Measures

Increasingly, research on survey methodology has been moving in the direction of assessing the reliability of single survey questions rather than composite variables (e.g., Groves, 1989; Saris and Andrews, 1991; Saris and van Meurs, 1990; Saris and Gallhofer, 2007; Scherpenzeel and Saris, 1997; Alwin, 1989, 1992, 1997, 2005, 2007; Alwin and Krosnick, 1991). Second, the idea of using coefficients that assume a composite measure of the underlying variable is unrealistic, and certainly so for assessing the reliability (or validity) of many types of latent variables. Standard internal consistency approaches, e.g., coefficient α, make no sense in most cases as an estimate of reliability of measurement.

MTMM Models

There is an increasing amount of support for the view that shared method variance inflates ICR estimates. One approach to dealing with this is to reformulate the CTST along the lines of a multiple-factor approach and to include sources of systematic variation from *both* true variables and method factors. With multiple measures of the same concept, as well as different concepts measured by the same method, it is possible to develop an *MTMM matrix* (see **Table 1**) and formulate a model that permits the decomposition of the observed variance in a unique trait–method combination into those parts that can be interpreted as *validity*, *invalidity*, and random error, or *unreliability*. The design requirements are stringent, in that one needs the measurement of K traits measured by each of M methods (generating $G = KM$ observed variables) (see Campbell and Fiske, 1959; Alwin, 1974). If such a design can be implemented, this allows the specification of a model such as that given in the following.

In order to specify the model for the MTMM design, we can formulate an extension of the common factor representation of the CTST given above as follows:

$$Y = \Lambda_{T^*} T^* + \Lambda_M M + E$$

where Y is a ($G \times 1$) vector of observed random variables, T^* is a ($K \times 1$) vector of 'trait' true-score random variables, M is an ($M \times 1$) vector of 'method' true-score random variables, and E is a ($G \times 1$) vector of error scores (see **Figure 1**). The matrices Λ_{T^*} and Λ_M are ($G \times K$) and ($G \times M$) coefficient matrices, respectively, containing the regression relationships between the G observed variables and the K and M latent trait and method latent variables. Note that with respect to the CTST model given above, $\Lambda T = \Lambda_{T^*} T^* + \Lambda_M M$. The covariance structure for the model can be stated as:

$$\Sigma_{YY} = [\Lambda_{T^*} | \Lambda_M] \Phi_T [\Lambda_{T^*} | \Lambda_M]' + \Theta^2$$

where Φ_T has the following structure:

$$\Phi_T = \left[\begin{array}{c|c} \Phi_{T^*} & 0 \\ \hline 0 & \Phi_M \end{array} \right]$$

Note that the specification of the model places the constraint that the trait and method factors are uncorrelated. The estimation of this model permits the decomposition of reliable variance in each observed measure into valid and invalid parts, which we do not have the space to discuss further here. Suffice it to say that there is a growing literature surrounding the application of these methods (see Alwin, 2007, 2011; Saris and Galhofer, 2007; Scherpenzeel and Saris, 1997).

Test–Retest Reliability

In past years, the 'test–retest' method was considered a valuable design for assessing reliability (see Siegel and Hodge, 1968), although early on there have been serious issues raised about its utility (Moser and Kalton, 1972). In some cases, it can be a quite valuable design; however, when the reinterview time period is so short that respondents can remember their earlier response, or when the reinterview period is so long that the respondents change, there are problems (see Alwin, 2007: pp. 96–101). It is probably worth noting in this regard that the test–retest design is not mentioned in the current set of standards for educational and psychological testing (AERA/APA/NCME, 1999). Investigators interested in the study of measurement error in survey data using longitudinal methods have turned to alternative designs and other models for reliability estimation, as we discuss in the following section.

Longitudinal Methods

Despite the critiques of the test–retest approach, it can be argued that for purposes of assessing the reliability of survey data, longitudinal data provide an optimal design (see Alwin, 2007). Indeed, the idea of replication of questions in panel studies as a way of getting at measurement consistency has been present in the literature for decades (see Heise, 1969; Wiley and Wiley, 1970; Jöreskog, 1970; Saris and Andrews, 1991). The limitations of the test–retest design are well-known, but they can be overcome by incorporating three or more waves of data separated by lengthy periods of time (see Alwin, 2007: pp. 96–116). The multiple-wave reinterview design discussed in this article goes well beyond the traditional test–retest design (see Moser and Kalton, 1972: pp. 353–354), and specifically, by employing models that permit change in the underlying true score (using the

Table 1 Multitrait-multimethod matrix for three traits and three methods

		Method 1			Method 2			Method 3		
	Trait	X	Y	Z	X	Y	Z	X	Y	Z
1	X	$r_{X_1 X_1}$								
	Y	$r_{X_1 Y_1}$	$r_{Y_1 Y_1}$							
	Z	$r_{X_1 Z_1}$	$r_{Y_1 Z_1}$	$r_{Z_1 Z_1}$						
2	X	$\mathbf{r_{X_1 X_2}}$	$r_{X_2 Y_1}$	$r_{X_2 Z_1}$						
	Y	$r_{X_1 Y_2}$	$\mathbf{r_{Y_1 Y_2}}$	$r_{Y_2 Z_1}$						
	Z	$r_{X_1 Z_2}$	$r_{Y_1 Z_2}$	$\mathbf{r_{Z_1 Z_2}}$						
3	X				$\mathbf{r_{X_3 X_2}}$	$r_{X_3 Y_2}$	$r_{X_3 Z_2}$	$r_{X_3 X_3}$		
	Y				$r_{X_2 Y_3}$	$\mathbf{r_{Y_2 Y_3}}$	$r_{Y_3 Y_2}$	$r_{X_3 Y_3}$	$r_{Y_3 Y_3}$	
	Z				$r_{X_2 Z_3}$	$r_{Y_2 Z_2}$	$\mathbf{r_{Z_2 Z_3}}$	$r_{X_3 Z_3}$	$r_{Y_3 Z_3}$	$r_{Z_3 Z_3}$

quasi-Markov simplex approach) allows us to overcome one of the key limitations of the test–retest design. And through the use of design strategies with relatively distant reinterview intervals, e.g., 2-year intervals, the problem of consistency due to retest effects or memory can be remedied, or at least minimized. There are two main advantages of the reinterview design for reliability estimation. First, the estimate of reliability obtained includes all reliable sources of variation in the measure, both common and specific variance. Second, under appropriate circumstances it is possible to eliminate the confounding of the systematic error component discussed earlier, if systematic components of error are not stable over time. In order to address the question of stable components of error, the panel survey must deal with the problem of memory, because in the panel design, by definition, measurement is repeated. So, while this overcomes one limitation of cross-sectional surveys, it presents problems like if respondents can remember what they say and are motivated to provide consistent responses. If reinterviews are spread over months or years, this can help rule out sources of bias that occur in cross-sectional studies. Given the difficulty of estimating memory functions, estimation of reliability from reinterview designs makes sense only if one can rule out memory as a factor in the covariance of measures over time, and thus, the occasions of measurement must be separated by sufficient periods of time to rule out the operation of memory.

The analysis of panel data in the estimation of reliability must be able to cope with the fact that people change over time, so that models for estimating reliability must take the potential for individual-level change into account (see Coleman, 1964, 1968; Goldstein, 1995; Wiggins, 1973). Given these requirements, techniques have been developed for estimating measurement reliability in panel designs where there are three or more waves, wherein change in the latent variable is incorporated into the model. With this approach, there is no need to rely on multiple indicators within a particular wave or cross-section in order to estimate the measurement reliability, and there is no need to be concerned about the separation of reliable common variance from reliable specific variance. That is, there is no decrement to reliability estimates due to the presence of specific variance in the error term; here specific variance is contained in the true score. This approach is possible using modern structural equation modeling (SEM) methods for longitudinal data and is discussed further in related literature (see Alwin, 1989, 1992, 2007; Alwin and Krosnick, 1991; Saris and Andrews, 1991).

In the general case of the quasi-simplex model for a single variable assessed in a multiwave panel study can be defined as:

$$Y = \Lambda_Y T + E$$

$$T = BT + Z$$

Here Y is a $(P \times 1)$ vector of observed scores, T is a $(P \times 1)$ vector of true scores, E is a $(P \times 1)$ vector of measurement errors, Z is a $(P \times 1)$ vector of disturbances on the true scores, Λ_Y is a $(P \times \mathrm{P})$ identity matrix, and B is a $(P \times P)$ matrix of regression coefficients linking true scores at adjacent time points. The general path diagram for the case of P overtime measures is given in Figure 2.

Figure 2 Path diagram of the quasi-Markov simplex model – general case ($P > 4$). Source: Alwin, D.F., 2007. Margins of Error: A Study of Reliability in Survey Measurement. John Wiley and Sons, New York.

For the case where $P = 4$, we can write the matrix form of the model as:

$$\begin{pmatrix} Y_1 \\ Y_2 \\ Y_3 \\ Y_{41} \end{pmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \times \begin{pmatrix} T_1 \\ T_2 \\ T_3 \\ T_4 \end{pmatrix} + \begin{pmatrix} E_1 \\ E_2 \\ E_3 \\ E_4 \end{pmatrix}$$

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ -\beta_{21} & 1 & 0 & 0 \\ 0 & -\beta_{32} & 1 & 0 \\ 0 & 0 & -\beta_{43} & 0 \end{bmatrix} \times \begin{pmatrix} T_1 \\ T_2 \\ T_3 \\ T_4 \end{pmatrix} = \begin{pmatrix} Z_1 \\ Z_2 \\ Z_3 \\ Z_4 \end{pmatrix}$$

The reduced form of the model is written as:

$$Y = \Lambda_Y [I - B]^{-1} Z + E$$

and the covariance matrix for Y as:

$$\Sigma_{YY} = \Lambda_Y [I - B]^{-1} \Psi [I - B]^{-1} \Lambda_Y + \Theta^2$$

where B and Λ_Y are of the form described above, Ψ is a $(P \times P)$ diagonal matrix of variances of the disturbances on the true scores, and Θ^2 is a $(P \times P)$ diagonal matrix of measurement error variances. This model for multiple-wave data (where $P \geq 3$) can be estimated using any SEM approach (see Heise, 1969; Wiley and Wiley, 1970; Alwin, 2007).

Conclusions

The purpose of this article was to provide an overview of some of the newer strategies for assessing the validity and reliability of social science data. There are some traditional notions about implementing assessments of data quality based on composite scores (e.g., Cronbach's α coefficient) that have most likely outworn their usefulness in the modern era. More recently, researchers have become oriented to the evaluation of the reliability and validity of specific questions, and other tools are now viewed as more useful. Although this article has pointed the reader in the direction of some of the available techniques, there are a number of practical considerations that must be addressed before any method can be used to adduce interpretations of the reliability and validity of measurement.

Abstract

Reliability of measurement refers to the dependability or repeatability of the measurement process: Does one get about the same answer when one measures a construct several times, or using similar methods of measurement, or using different people? Relevant theory comes from classical test theory, item response theory, generalizability theory, and related statistical methods. Classical test theory and generalizability theory are theories of the performance of a whole test or instrument (e.g., questionnaire), whereas item response theory deals with the behavior of individual test items as well as the whole test.

Introduction

Whenever an aspect of human behavior is measured, the question that always arises is: How good is the measurement process? In the behavioral sciences, conceptual and statistical models for answering that question are generally divided into two major categories: *reliability* and *validity*. As a first approximation, one may think of validity as being concerned with whether the right construct is being measured, and reliability as being concerned with the issue of how well we are measuring whatever it is that is being measured (regardless of whether or not it is the right quantity to measure). When choosing a measurement method, one must consider both of these issues; the total error of measurement comes from both the unreliability and invalidity of a measure. Although this article concentrates primarily on reliability, it also discusses the measurement process as a whole and the relationship between reliability and validity issues.

As with many terms, the scientific and psychometric uses of the word 'reliability' derive from, but are different from, the everyday use of the term. In everyday life, a car would be considered reliable if it started every time. If the word were used in the technical sense, one would also say that a car was reliable if it never started; it would be unreliable only if it sometimes started and sometimes did not. The technical term, in other words, is more concerned with the *consistency* of behavior and its measurement, regardless of where the behavior is on a scale. The main question is whether one gets the same answer every time a measurement of an individual is made. Whether that measurement is then useful is a question of validity; a measurement procedure could be perfectly reliable but useless.

Reliability theory generally begins with a conceptual framework, which is then translated more formally into a statistical model. Most reliability theory is concerned with a particular type of measurement instrument, multiple-item tests, and some theory is applied in an even more limited setting of items that are scored dichotomously as true or false. The three most commonly used models are (1) classical test theory (CTT), based on factor analysis; (2) generalizability theory (GT), based on analysis of variance (ANOVA); and (3) item response theory (IRT), based on latent trait models. Other statistical methods usually are needed for dealing with measurements that are either not tests, such as observations of behavior, or are not multiple-item tests. Much of measurement theory (and terminology) derived originally from consideration of ability tests, but the theory applies equally well to many other areas of behavior such as personality assessment.

Classical Test Theory

CTT is based on the assumption that a single underlying dimension (a trait or skill) is being measured, and that every person has a single true score, T, on that dimension. The underlying dimension or test domain may be more or less 'pure'; for example, one might think of skill in (1) doing multiplication of 3-digit numbers; (2) solving algebra word problems; or (3) solving college mathematics problems. The important consideration is that all items on the test are measuring this skill or trait, and that the skill or trait is well defined. Each person's observed test score, X, is assumed to be determined by his or her true score T plus some error of measurement, e, which would either raise or lower the observed score relative to the person's true score. The basic equation of CTT is, therefore,

$$X = T + e \qquad [1]$$

in which the quantities are as defined above, and the errors are assumed to have a mean of zero and to be uncorrelated with (unrelated to) T.

What exactly does T represent? Conceptually, the definition requires a bit of imagination and tolerance for ambiguity. Imagine a person being tested over and over again, using different sets of items selected from the collection of all items designed to measure the underlying construct. (A test may consist of any number of items, including the special case of a single item, such as an essay.) The average of all these scores (more technically, the expected value) is the person's true score T.

The first major consequence of this model is that the variation among people on observed test scores (σ_X^2) is the sum of the variation in true scores (σ_T^2) and the variation in the errors of measurement (σ_e^2); that is,

$$\sigma_X^2 = \sigma_T^2 + \sigma_e^2. \qquad [2]$$

The optimal case occurs when the error for each person is zero; then there is no variation in errors, so $\sigma_e^2 = 0$. Consideration of this equation leads to the definition of reliability as

 http://dx.doi.org/10.1016/B978-0-08-097086-8.44050-X

the proportion of total variance in scores that is attributable to true variation rather than error variation; that is,

$$\text{Reliability} = \sigma_T^2/(\sigma_T^2 + \sigma_e^2) = \sigma_T^2/\sigma_X^2. \quad [3]$$

For example, if the true score variance were 8 and the error variance 2, the total variance would be 10, and the reliability would be $8/10 = .80$. One useful interpretation of this number is that it is the square of the correlation between true scores (T) and observed scores (X).

Among the interesting implications of the CTT model is that a test can be made more reliable by making it longer; adding items increases the true score variance at a faster rate than the error variance. One aspect of test design is determining how long a test must be to have a reliability great enough for the intended uses of the test.

Another implication of the model is that the reliability of a test is not a single number but depends on how individuals who took the test were sampled. If a broad range of people are sampled, so that the true score variance is large, then the reliability will be greater than if people with a more limited range of true scores are sampled. (This is because the error variance would be the same in each case.) For example, if a test were given to all high school seniors, it would have a higher reliability estimate than if it were given only to seniors who planned to attend a highly selective college or university.

Estimation of Reliability

Unfortunately, because true score and error variation are not directly observable, the definitional eqn [3] above cannot be applied directly. However, this conceptualization and the accompanying statistical model lead to several possible methods of estimating reliability. First, one could randomly divide any multiple-item test into two halves and see how the scores on one half relate to the scores on the other half. If a test were perfectly reliable, each person would get the same score on both halves of the test. Of course, the correlation is never perfect; the observed correlation allows the calculation of an estimate of the reliability of the whole test. Other methods use the correlations among the items to estimate reliability. These methods, including Cronbach's alpha (developed from an idea of Louis Guttman), are based on the same conceptual and statistical principles as the split-half coefficient.

Because each person is measured at one time point, any variability due to changes in that person across time are ignored by these methods. Here is where the definition of true score becomes critical. One can think of 'true' changes in true score (due to learning or forgetting in between testing times); one can also think of more temporary changes, due to illness, noise, or distractions in the testing room, and so on. In addition, some characteristics are expected to be variable over time, including measures of mood. In personality psychology, the more stable characteristics are called *traits*, while the more labile characteristics are called *states*. In CTT, the temporary effects are included in errors of measurement, whereas changes in traits generally are not. In spite of this conceptual uncertainty, this suggests another commonly used strategy for assessing reliability: Give the same test to a group of people at two different times and see whether their scores are closely related. For obvious reasons, this is called test-retest reliability. Of course, one assumes that the first measurement does not affect the second measurement, which may or may not be the case and which must be considered. To minimize the effects of 'true' changes in true scores over time, the time periods between testings must be kept relatively short.

A related method uses two or more forms of a test, with each form being constructed in an identical manner, so that the forms will be as nearly alike as possible. If in fact they have the same means, variances, and reliabilities, then they are said to be *parallel tests*. If one administers two such forms to the same group of people (e.g., on two consecutive days), the correlation between scores on the forms is called a parallel test estimate of the reliability.

In addition to measuring the overall performance of the test, one is also interested in how well the score of each individual has been estimated. The *standard error* of the test score is such a number; if small, the score is a more accurate estimate of ability than if the standard error is large. As an example, suppose a person has a score of 120 on an IQ test, and the test has a standard error of 5 points. Then we can construct a 95% confidence interval around the estimate by adding and subtracting 2 standard errors (10 points, in this case); here the interval is from 110 to 130. This means, roughly speaking, that there is a 95% chance that the interval will contain the person's true score.

Besides considering the reliability of the test as a whole, one must also consider how good each item on the test is. The most commonly used method to assess this in CTT is the item total correlation, which measures how well the item discriminates among people of varying skill or ability levels. To calculate this, one correlates scores on the total test (usually with the particular item omitted) with scores on the item (with 0 used for an incorrect response and 1 for a correct response). In other words, an item is good if people who score high on the test tend to get the item right more often than do people who score at lower levels on the test. An item would be considered bad if people with low scores on the test are just as likely to get the item right as people with high scores on the test. In the test construction process, items that have low-item total correlations are generally omitted or rewritten.

Another common item statistic is the proportion of test takers who get the item right; this is usually called the *difficulty* of the item (though the term *facility* would be more appropriate). Although it is commonly reported, it is of little relevance to reliability; item difficulties are more important when trying to tailor a test for various ability levels or to compare the characteristics of tests that are supposed to be equivalent (parallel, in technical terms).

Weaknesses of CTT

CTT has several weaknesses that have led to the development of other models for test scores. First, the concept of reliability is dependent on the group used to develop the test. If the group has a wide range of skills or abilities, the reliability will be higher than if the group has a narrow range of skills or abilities. Thus, reliability is not invariant with respect to the sample of test takers and is therefore not a characteristic of the test itself. In addition, neither are the common measures of item discrimination (such as the item total correlation) or item difficulty (percent getting the item correct). As if this were not bad enough, the usual assumption that the standard error is the same for test takers at

all ability levels is usually incorrect. (In some extensions of CTT, this assumption is dropped, but these extensions are not well known or widely used.) CTT also does not adequately account for observed test score distributions that have floor and ceiling effects, where a large proportion of test takers score at either the low or the high end of the test score range.

CTT has difficulties in handling some typical test-development problems, horizontal and vertical equating. The problem of *horizontal equating* arises when one wishes to develop another test with the same properties as (or at least with a known relationship to) an existing test. For example, students who take college admissions tests such as the ACT or SAT should get the same score, regardless of which version of the test they take. *Vertical equating* involves developing a series of tests that measure a wide range of ability or skill. For example, although one could develop completely independent tests of arithmetic for each elementary school grade, we might instead want to link them to have one continuous scale of mathematical skill for grades 1 through 6. Vertical and horizontal equating are not impossible within CTT, but they are much more straightforward with IRT.

These problems of CTT are caused partly by some fuzziness in the theory (the population to be sampled is usually not considered in any detail in the theory). But they are also due to the failure of most data collection to be carried out on a random sample of any population, let alone a population considered appropriate for the test being investigated. In practice, convenience samples are used. They generally fit some criteria that the investigator specifies but are otherwise taken as they are available to the researcher. Finally, CTT as originally conceptualized was never intended to address some of the practical testing problems described above.

Generalizability Theory

CTT provided a framework that has proved useful in a number of situations, but psychometricians realized many of its limitations even as they were developing the theory. Most important, they realized that a wide variety of factors can influence observed test scores, including how the items were generated, how the tests were administered, and how the items were scored (especially if they were free responses scored by raters). In CTT, all these factors were included in the (one and only) error term in the statistical model. To include these factors in their statistical models, psychometricians developed what is known as GT, which included more than one source of error in test scores.

GT is based on the statistical methods of ANOVA. Factors thought to have major influences on test scores are included in a design, and the analysis allows the researcher to determine how much influence each factor has on variation in test scores. GT allows the computation of various estimates of reliability, depending on which factors are considered important for a particular use of the test.

As an example, consider a test of writing in which each student writes three brief essays, each of which is scored by two raters. GT allows the estimation of how much variation in test scores is due to variation in essay topics and how much is due to variation in raters.

Like CTT, GT is concerned primarily with the behavior of the test as a whole, rather than the performance of components, such as subscores or items.

For further details on GT, see the article in this volume. The classic source on GT is the book by Cronbach et al. (1972). Brennan (2011) and Shavelson et al. (1989) provide a less technical overview.

Item Response Theory

The past few decades have seen a steady rise in the use of IRT to solve some of the problems that CTT could not deal with adequately. IRT, like CTT, is based on an assumption that a single underlying dimension is being measured. But the basic conceptual idea behind IRT is the relationship between the score (usually right/wrong) on an item and the underlying dimension, whereas CTT is based on the relationship between total test score and the underlying dimension. This relationship, represented by an item characteristic curve, or ICC, shows how the probability of getting the item right (for dichotomous items) changes with the underlying trait. The probability cannot be below zero or greater than one, so the ICC generally has an elongated S shape. In three-parameter models, the items may differ in whether the curve starts at zero for people of very low ability (no guessing) or above zero (if guessing correct is likely); how fast the curve rises (discrimination); and whether the curve is to the left (easy), in the middle, or to the right (hard). In two-parameter models, only discrimination and difficulty are used; guessing is fixed at zero. And for one-parameter (Rasch) models, only difficulty is used; guessing is fixed at zero and discrimination at one for all items.

IRT models solve many problems that were difficult for CTT, including the ability to construct a different test for each test taker, so that students at all levels of ability can be assessed with items appropriate to their status. Such adaptive tests, generally administered by computers, are becoming standard in many large-scale testing situations in some countries, including the Graduate Record Examination and licensing examinations in many fields.

In IRT, the traditional concept of reliability has no place. Instead, the emphasis is on the more basic concept of standard error of measurement; that is, how accurately has a test taker's true score been estimated? For a fixed test given to a group of examinees, the test characteristic curve shows the standard error for each level of ability. Unlike the simplifying assumption of CTT, the standard error can vary with ability. For example, if a test is relatively easy, the standard error will be smaller for students of low ability levels because the test is better matched to their abilities; students with higher abilities will not be well measured by an easy test.

For more information about IRT, see Thissen and Steinberg (2009).

Reliability in Criterion-Referenced Measurement

In some measurement situations the primary interest is in determining whether a person meets a predetermined standard or

criterion. These judgments are sometimes made for individuals (e.g., Is my student Karol reading at grade level?) and at other times for groups (e.g., What proportion of eighth-graders is reading at or above grade level?) In everyday life, a driver's license test provides a familiar example of a criterion-referenced test. In education, the theory of criterion-referenced measurement was developed to provide a suitable technical scaffolding for making such judgments.

Again using the concept of consistency as a basis for conceptualization, reliability of criterion-referenced measures is concerned with issues such as whether an individual would receive the same classification if tested by different raters, on a different form of the test, or on different days. It is clear that the consistency will depend on how close the individual's true score is to the cut-point determining mastery. If a person is well above or below the cut-point, decisions will tend to be more consistent than for people near the cut-point. In the extreme, if a person's true score is exactly at the cut-point, then that person will pass half the time and fail the other half, no matter how well the test is constructed.

Because of the 'yes/no' nature of scoring, criterion-referenced test theory is somewhat different from the usual CTT but only because some different statistical methods are appropriate for these types of data. Criterion-referenced measurement is also more obviously concerned with decisions made on the basis of a test; other test theory models are only implicitly concerned with such decisions.

For more information about criterion-referenced measurement, see Hambleton et al. (1978), Harris et al. (1974), and Popham (1978).

Issues for Observational Measures

Many characteristics can be assessed by tests and questionnaires, but others are better assessed through observation of behavior. Behavior can be assessed by direct observation, or it can be recorded for later coding into categories. The recording can be more or less direct, ranging from video and audio devices to the memory of observers about past behavior (where the recording is in the mind of the observer).

Behavioral observations tend to take place in 'real-world' settings and generally (but not always) in uncontrolled conditions. Unlike tests, when those taking them know and expect that their behaviors are being observed, in natural settings one can imagine a range of possibilities for reactivity to the act of being observed. The more unobtrusive the observations, the more confidence one has in the quality of the measurement (though this generally would be classified as affecting validity rather than reliability). The classic reference on unobtrusive measurement is Webb et al. (1966).

Some issues tend to arise much more frequently in cases of observational measures than in tests and questionnaires. One such issue is the decision about whether to consider a characteristic being assessed as being categorical or continuous. For example, one might want to say that a person is either depressed or not, rather than being given a rating on a (nearly) continuous scale from not at all depressed all the way through extremely depressed. In such a case, the underlying trait is categorical, and different statistical methods are required. The most commonly applied method in this case is latent class analysis, which has been used in settings as diverse as determining stage of development of children, psychiatric diagnosis, and medical diagnosis.

One also tends to see different types of observed measures in observational data. Sometimes a variable has unordered categories, as would be the case if one classified a student in a class as either sitting quietly, sitting but making noise, or being out of his or her seat. Other times a variable may be a count or a rate, such as the number of times a student is out of his or her seat or the number of such times divided by the amount of time during which he or she was observed.

Typically, there are multiple observers of behavior or multiple coders of recorded behavior or both. (This can, of course, occur for certain types of tests, not just in behavioral observations. Essay tests are a common example, because multiple raters are often used. Similarly, portfolio assessments of students' work is often based on the judgment of multiple raters.)

These considerations present additional problems that affect the reliability of observational measures. Although consistency remains the primary concern, and the reliability (and validity) of behavioral observations depends on many of the same factors as for tests, additional factors of observational methods include the length of the period of observation, the conditions under which observations are made (including irrelevant stimuli), and the observers, raters, and coders used.

As one might infer from the discussion of GT, observational measures usually have more than one possible source of error, unlike that which is assumed in CTT. In addition to interobserver agreement problems, observers can make their observations at different times, in different settings, and under different conditions; all of these contribute to the error of measurement. GT allows researchers to estimate how much variability in the observations is due to each of these potential sources of error.

These differences from typical test data have additional implications for the statistical theory and data analysis methods generally used with observational data. When data come from observers, the issue of reliability is primarily a matter of whether two or more observers would come to the same conclusion (or, if a rating, the degree to which they agree) and whether the conclusion depends on when and for how long the observation occurs. For variables that fall into categories, one apparently simple method is to calculate the proportion of instances in which two raters or observers agree with each other about the category into which a particular observation should be placed. Unfortunately, the simplicity is only apparent, because for behaviors that are either rare or very common, a high percentage of agreement can occur by chance. For example, if a student is classified as being out of seat on 10% of occasions by each observer (and in seat the other 90%), the observers would agree 82% of the time, even if they were responding independent of the actual behavior. Therefore, such measures are typically corrected for chance agreement. Additional complications arise when there are three or more observers and when the observers do not rate or observe for the same period of time.

Details on statistical methods suitable for analyzing observational data are found in Suen and Ary (1989), and issues of

reliability and validity in ethnographic research are discussed in LeCompte and Goetz (1982).

Relationship of Reliability to Validity

In CTT, one cannot have a validity of a test that is higher than the square root of the reliability. This has led some to conclude that the reliability is more important than the validity of a measure because a test cannot be valid if it is not reliable. Although a test cannot be valid if its reliability is zero or extremely low, it is possible for one test to have a higher validity coefficient than another, even though the first is less reliable. Suppose that two tests (or other measures) are not actually measuring the same true score because they are measuring different traits. Then the one with lower reliability can have a higher validity if the trait it measures is more closely related to the outcome that the tests are meant to predict. For example, a paper-and-pencil test of rock-climbing skills might have greater reliability than a performance test done on a climbing wall in a gym, but the latter might still have greater validity as a predictor of performance in an actual rock-climbing situation.

The (invalid) conclusion about the relationship of reliability and validity has often caused strain between quantitative researchers and qualitative researchers. Qualitative researchers often use measurement procedures that have lower reliability than the procedures devised by quantitative researchers, but the qualitative researchers prefer these less reliable measures because they are measuring what the researchers want to measure. It is quite possible that in many cases they are right, and their less reliable measures have greater validity than certain measures that are more reliable.

Suggestions for Further Reading

Martin and Bateson (1986) is a short introductory work on measuring behavior. The two most popular undergraduate texts on measurement are those of Anastasi (1988) and Cronbach (1990). Nardi (2006) discusses reliability in a less technical manner. At a higher level are texts by Crocker and Algina (1986), Allen and Yen (1979) and Alwin (2007, 2010), and the general reference work edited by Linn (1989). McDonald (1999) is a newer text that provides a unified treatment of many issues in test theory. At a very advanced level, Lord and Novick (1968) and Bohrnstedt (2010) are texts on both CTT and IRT. A more modern text on IRT is Hambleton and Swaminathan (1984); simpler versions include Hambleton et al. (1991) and Sharkness and DeAngelo (2011).

Religion and Abuse

Nancy Nason-Clark, University of New Brunswick, Fredericton, NB, Canada

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Abuse occurs both in families of faith and within families holding no expressed religious convictions or practices. When abuse and religion are linked, the experience is profound for those who are victimized – whether it is a battered wife or a boy who is sexually abused by his parish priest. This entry explores some of the dynamics of abuse in families of deep religious faith, as well as the resources available to assist those who have been impacted.

According to the 'Religion and Violence e-Learning' web-based training, (www.theraveproject.org), abuse is behavior that shatters dreams and causes pain. It can involve physical violence like hitting, kicking, or choking. It can include name-calling or harsh words that are meant to hurt. Sometimes, it involves limiting or denying access to food, or money, or other family resources. Abuse can involve demands for sexual activity. However, abuse always involves responses that are meant to control, shame, or humiliate another person through intimacy and shared experience. Peace and safety for all family members cannot exist when abuse is present. Spiritual abuse – the attempt to impair or belittle a person's spiritual life or spiritual well-being – includes preventing him or her from performing spiritual acts or causing him or her to transgress spiritual obligations or prohibitions (Dehan and Levi, 2009; Sevcik et al., forthcoming). For highly religious women, spiritual abuse can accompany physical, emotional, and other forms of abusive behavior (Nason-Clark et al., 2013).

Victims write about abuse as a pattern of coercive controlling behavior that is directed at one intimate partner by the other (Owens, 2008). While women are its most common victims, at least in heterosexual relationships, any person can be a victim. Domestic violence is rooted in the desire of one partner to gain and maintain, power and control over the other. Many survivors refer to the betrayal and emotional abuse as the most damaging to them (Nason-Clark and Kroeger, 2004). Long after the broken bones have healed, the angry harsh words continue to erode the victim's sense of self-worth. Domestic violence that strikes at home is the training ground for future abuse. Children who grow up in families where they witness or experience abuse, are far more likely than those who have not suffered this experience, to be victims or perpetrators of similar abuse as adults.

The Prevalence and Severity of Abuse

Approximately one in four women around the globe has been physically abused by an intimate male partner, such as a husband or ex-husband. In fact, a woman is more likely to be injured, raped, or physically threatened by a current or former partner than by a stranger or another person. Studies differ in their funding base, their research design, the exact wording of the questions, and how the research instruments are administered; yet in every country of the world where data have been collected, the evidence is overwhelming: large numbers of women suffer physical violence from the men with whom they have exchanged marriage vows or shared intimacy and residence (Kroeger and Nason-Clark, 2010).

The US Centers for Disease Prevention and Control (CDC) report on their website that among victims of intimate partner violence, about one in four women and one in seven men have experienced severe physical violence by an intimate partner (e.g., hit with a fist or something hard, beaten, slammed against something) at some point in their lifetime. This has led Dr. Howard Spivak, the Director of Violence Prevention at the CDC to state: "Intimate partner violence, rape, stalking – all of these forms of violence can create toxic stress on the body that is long-lasting and cumulative, and can negatively impact a person's health and well-being for the rest of their life." (http://www.cdc.gov/violenceprevention/nisvs/index.html)

In Canada, (between 2000 and 2005), 653 000 women reported being victims of spousal violence, with 26% of these women being assaulted more than 10 times. Statistics Canada (2005) data reveal that younger women are at higher risk: women between the ages of 15 and 24 reported the highest one-year rates of spousal violence. Aboriginal women are also more likely to experience abuse in an intimate relationship; they are three times more likely to be victims of spousal violence than nonaboriginal women (Statistics Canada, 2008).

There is a tendency for many victims to minimize or deny the abuse, leading to the assumption that the abuse reported in country by country surveys is just the tip of the iceberg. Many staff in policing services and in the 'transition house' movement believe that the reporting of domestic violence in the United States (and in other Western countries) may have increased in recent years, largely because of enhanced training for first responders (like the police) and greater awareness amongst the public. There is ample evidence that in countries around the world, abuse impacts many women – and they often suffer in silence, experience deep shame, and harbor a sense of hopelessness about the future (Nason-Clark and Kroeger, 2004).

Understanding the Dynamics of Abuse

Fear is the most common response amongst victims of domestic violence. There is fear that the violence could escalate and fear of reprisal if they should tell someone. Fear leads to

secrecy. So much energy can be taken up by trying to pretend that everything is alright at home that there is little energy left over to take action. Many women are economically dependent on the men who abuse them. Others cling to the promise of changed behavior. Some women feel that they must stay in the marriage no matter what the cost. Religious women who are Christian sometimes believe it is their personal 'cross to bear' or that they are called upon to be a 'suffering servant' (Sevcik et al., forthcoming). Many women report that they remain in a marriage, despite the abuse that is suffered, on account of the children. Others lack adequate support systems if they decide to flee violent homes. For aboriginal women, immigrant women, and especially African American women in the United States, the fear of incarceration of their partner deters them from reporting the abuse or leaving a violent relationship. On the whole, women who are abused want the violence to stop but not for the relationships to come to an end. Faith traditions are sometimes guilty of encouraging women to return to relationships – even violent ones – after being offered advice that their changed behavior will lead to cessation of the abuse.

Violence is a learned behavior, and a substantial proportion of abusive religious men have experienced, or witnessed abuse in their childhood homes (Nason-Clark and Fisher-Townsend, forthcoming). As a result, the cycle of violence is passed from one generation to the next. Substantial numbers of the next cohort of abusive men are now young boys watching their mothers suffer. Children cannot flourish where abuse abounds. It affects how they perform at school, relate to friends, view family life, and feel about themselves. Abuse in the home creates an environment that threatens the physical and emotional health of all family members and leaves children especially vulnerable. Some abusers are determined to alter their violent ways and seek, with the support of the wider community, to change their behavior; and many abusive partners use religious language in an attempt to convince their wives, probation officers, pastors, or facilitators in batterer intervention programs (BIPs) that they are serious about altering their abusive behavior. Often, there are other issues, like substance or alcohol abuse, which need to be part of the perpetrator's overall plan for changed behavior.

Domestic Violence and Communities of Faith

When abuse strikes within religious families, many women seek the help of their religious leaders or other women of like faith. This is true within the Christian community, for women as diverse as Baptists, Pentecostals, Methodists or Roman Catholics; but it is also true for Jewish women and for Muslims. It is often a tightly guarded secret that a woman carries within herself, bearing the shame and the fear and other emotions created by living in a home environment where her safety and emotional health cannot be assured. Some abused women disclose their problems to their religious leaders in the privacy of the pastoral study, but many religious women choose other women of faith as their first point of contact in revealing the story of domestic violence.

Governments around the globe are recognizing the devastating consequences of abuse – especially violence against women and children – and public money is beginning to be directed toward a greater understanding of the problem of abuse, reforming judicial systems to respond more quickly, and providing health and other social services to those impacted. Yet, many religious organizations – churches, mosques, synagogues, and other houses of worship – have been slow to recognize and respond to the call for faith communities to be part of the solution to domestic violence, rather than be part of the problem. A so-called 'holy hush,' pervades many religious organizations (Nason-Clark, 2000). It can be observed when religious leaders do not name violence in the family context directly and choose rather, to call it family conflict, disagreements, or problems of communication. It occurs when religious leaders are unaware of the resources in their own local region to assist a woman in crisis – whether those resources are linked to the criminal justice system or advocacy agencies, like transition houses or shelters. Most religious leaders have never preached a message that explicitly condemns abuse in the family and many pastors, priests, and other faith leaders do not include any information about abuse in the information they offer to couples about to be married. Youth leaders within religious organizations too, often neglect to encourage young men and women to identify and then practice healthy interpersonal encounters with others of their own age. Finally, when women or men who have been victimized come to their faith communities for help, pastors, rabbis, and others in leadership roles are often reluctant to refer them to outside community resources, fearing that the experts outside the faith might challenge the faith perspective rather than focus on the cessation of abuse and the journey toward healing and wholeness.

Yet, when religious leaders employ both the language of their faith tradition and the contemporary cultural language of safety, empathy, and justice to condemn abuse and respond with compassion to victims, the result could be very effective. Religious leaders are able to speak words of comfort to victims and words of accountability to offenders that have the potential to offer help beyond that available at the level of community-based agencies. When priests, ministers, rabbis, and imams speak out against violence, they use their moral authority to bring healing to victims and call those who act abusively to accountability. This is a crucial aspect of ending the 'holy hush,' which denies the presence, potential, and long-term consequences of violence in families of faith.

Unique Vulnerabilities Facing Religious Battered Women

Religious women – Christian, Jew, and Muslim alike – tend to be very reluctant to see themselves as battered wives, even when they experience repeated and severe physical abuse at the hands of their intimate partners (Alkhateeb and Abugideiri, 2007; Dehan and Levi, 2009; Sevcik et al., forthcoming). Like most women, they feel afraid for themselves and their children and fear reprisal if they leave or seek assistance. But religious women also tend to be very forgiving, are more prone to blame themselves, and believe often that they have promised God (and their extended family network) that they will stay married until death. They also experience both the fear and

reality of rejection in their religious communities when they disclose the abuse and when attempts to repair the relationship fail.

The resources that abused religious women seek in the aftermath of domestic violence also differentiates them from other abused women. Since many communities of faith cling to traditional notions of gender and family life, and celebrate 'family values,' religious battered women have to take even more responsibility than other women for attempting to hold the family together no matter what the cost to them personally. Sometimes this is linked to notions of family honor, for others, it is intertwined with notions of the cost of discipleship. Victims are often reluctant to seek secular, community-based sources of support, preferring to look to others who share their faith perspective when the crisis comes home.

As a result, it is imperative that those in the helping professions (like therapists, domestic violence advocates, the police, and legal advisors, to name but a few) understand some of the specific needs of clients who are very religious. Often spiritual needs are primary in the aftermath of violence at home. And there are many questions that surface, questions that require answers from someone with either spiritual credentials or knowledge of the specific religious tradition with which the family is connected. Whether a religious victim of abuse first seeks help in her faith community, or from an agency in the broader society of which she is a part, she should be able to expect that her story of abuse is taken seriously; that she is given accurate, practical advice; that her safety and security are paramount; and that her faith is understood and respected. For highly religious women, the experience of domestic violence is so intertwined with the experience of personal faith that it would be impossible to understand one as separate from the other. A successful outcome will need to take into account both the experience of violation that a victim has endured and the victim's deeply held faith and practices. Cultural and religious competency is needed from those who work in supportive services, but this is rarely extended to abused women from any of the major faith traditions, who are very religious.

Responding to Abusive Religious Men

Imperative features of any intervention services offered to men who abuse their wives or intimate partners are the issues of accountability, justice, changed beliefs, and behavior. Most men who attend BIPs, come because the criminal justice system has mandated that they do so. It usually occurs as part of the sentencing after a conviction for domestic violence. A few men are referred to a program by a therapist, a religious leader, or their partners, as a final stage in the process of considering the end of the relationship.

Religious women who were abused are often very hopeful that intervention programs and services will change the violent men with whom they are in relationship. Since many abused religious women want the relationship to continue and avoid divorce, they often have faith that these interventions will change their abusive partners. While there are very few faith-based or faith-enriched batterer intervention services, the scant evidence that has been collected suggests that when religious leaders hold religious men accountable for their abusive acts and encourage them to follow through on court-mandated treatment options, those men are more likely, than men not so encouraged, to complete the program in its entirety (Nason-Clark et al., 2004). This is no small matter as program completion in all BIPs is an enormous challenge.

In any intervention services for religious men who act abusively, it is important that at least one of the facilitators or staff at the agency involved, is able to respond using the language of the participant's faith traditions. This enables facilitators to counter any claims made by program participants that their sacred books or traditions justified the abuse or violent acts toward their partners. This ability could help programs hold religious men accountable for their actions. Religious faith can be an important variable in helping violent men become accountable and do the work required for change; and faith leaders are an important, yet unrecognized-resource in community-based responses to domestic violence (Nason-Clark and Fisher-Townsend, forthcoming).

While scholars have argued for some time that it is critical to see the centrality of the religious belief system in the lives of many men who are violent, it has not become a key component of service delivery. Yet, faith is a central ingredient in understanding the assumption of male entitlement, power, and control that fosters abuse, and it must be part of the solution to domestic violence.

The Challenge for Religious Leaders in Responding to Abuse

Studies that investigate the response of religious leaders to abuse have reported that Christian pastors and priests claim that their training has not adequately prepared them to understand the prevalence and severity of abuse, its long-term consequences, or the spiritual dimensions that often surface in the life of a victim or an abuser. The same can be said for religious leaders in other faith traditions. Even seminarians currently enrolled in higher education programs note that they do not feel equipped to respond to families impacted by abuse (McMullin and Nason-Clark, 2011, 2013). Many victims, as well as perpetrators, look to their faith communities in the aftermath of crises at home: religious leaders, then, become the gatekeepers to sources of support and referral options. If the clergy denies or minimizes the abuse, the woman or man who has come for help often will not seek assistance elsewhere. Members of the clergy who are aware of the issue of domestic violence and are connected with a broad range of community-based resources, can identify and use their faith traditions to help both survivors and those who act abusively.

Religious leaders who lack knowledge about abuse are less likely to make referrals and more likely to see the problems in spiritual terms alone. This has the potential to increase the safety risk for a victim and often fails to bring the abuser to justice and accountability. Many religious leaders – Christian, Jewish, and Muslim – are strong supporters of family connectedness and they are reluctant to see any couples divorce or separate. Yet, often, living apart at least temporarily, is exactly what needs to happen to ensure the safety of all. Because the clergy tends to have little training

on the issue of abuse; often mistrusts broader community-based resources; and lacks specific faith-based resources; it often misunderstands the relationship dynamics that lead to abuse. Moreover, for some religious leaders, translating the rhetoric of happy family living into practical assistance for families in crisis seems overwhelming. It can be difficult for untrained members of the clergy to know how to harness their religious traditions to promote safety, justice, and accountability.

The Challenge for Community-Based Agencies in Responding to Religious Clients and the Power of Collaboration

Many workers in community-based agencies find it difficult to intervene in cases where clients are very religious. Many staff members do not have the specific knowledge that would allow them to work in a culturally competent manner with people from diverse religious backgrounds. Thus many victims of abuse may not feel safe in disclosing to a community-based agency that they are highly religious. In part, some of the challenges for secular workers intervening in cases involving highly religious women, may be the result of workers blaming the religious tradition for the violence or being unable to challenge religious beliefs used to justify abuse in particular faith traditions. Building bridges between community agencies and religious congregations is a very important initiative for responding to the prevalence and severity of abuse in the context of highly religious families. A coordinated approach between criminal justice workers (like the police, the courts, probation services), therapeutic staff (like social workers), domestic violence advocates, and religious leaders helps to ensure that the response to domestic violence takes into account cultural and religious characteristics leading to safe outcomes.

There are many web-based and print resources, as well as video documentaries, that have been created to assist religious women who are victims of domestic violence. Examples include The Religion and Violence e-Learning Project (www.theraveproject.org), the Faith Trust Institute (www.faithtrust.org), and Jewish Women International (www.jwi.org). Excellent documentaries include those produced by Diva Communications (www.divacommunications.com/programs/i-believe-you/) and Day of Discovery (www.rbc.org). Many of these organizations, including the Muslim-initiated Peaceful Families Project, produce brochures for washrooms located in houses of worship, shoe cards identifying how to contact a help line or shelter, bulletin inserts for Family Violence Awareness month, materials for religious leaders to use in premarital counseling, as well as curriculum for youth meetings.

When Religious Leaders Abuse

For the last 25 years, the public has been inundated with press stories of religious leaders who have abused the trust and respect of those they were supposed to serve. These abusive religious professionals claimed a divine calling to a ministry of compassion, usually at the parish or congregational level. The story line is familiar: a beloved priest or pastor; a victim initially grateful for the extra time or attention the religious leader offered; an unsuspecting congregation; secrecy and denial; an unrepentant religious hierarchy intent on concealing any wrongdoing on the part of its ordained staff; confusion and mixed messages between judicial and religious inculpatory processing of the allegations (with the later possibility of charges); very little emotional (not to mention financial) support for victims, their families and the congregations directly impacted by the tragedies; mounting legal costs; and long-term consequences for those who have been violated and betrayed.

The impact on victims and their families cannot be overstated. At the deepest level, for the adolescent victims, it was a betrayal of trust that had physical, emotional, sexual, and spiritual implications. Parents, relatives, and the broader Roman Catholic community shared secondary victimization of the clergical malfeasance (Shupe, 1995). For many years after the judicial sentencing and the Commissions and government-sponsored inquiries that followed, the parishes where priests had been charged faced the aftermath of the scandal. Often congregational members had been vocal supporters of individual priests and hostile critics of those who disclosed the abuse. Once the allegations turned to charges and then to convictions, there was extreme embarrassment and outrage directed toward the church and its leaders. Particularly painful was the fact that often Bishops and others in the clerical hierarchy knew of the proclivity of a particular religious leader to be errant. When given a choice, those clerical dignitaries ignored the pain and suffering of victims, their families, and the congregations where the errant priests were placed in ministry; and chose instead to protect the reputation of the malfeasant priest and the broader institution of which he was a representative. Often the priest was moved from one parish to another without even a hint of his sexually abusive behaviors toward minors being noted.

Disclosures of sexual abuse at the hands of Roman Catholic priests have been mounting since the 1980s. This is true across Canada, the United States, Ireland, Germany, and in many other parts of the developed world. There is mounting evidence that there were strategic cover-ups by the Roman Catholic religious hierarchy, and a lack of compassion and justice for victims and their families. But, sexual abuse and sexual misconduct, has not been linked only to the Roman Catholic religious elite.

Diana Garland has conducted a major research initiative to explore sexual misconduct in the clergy more fully (www.baylor.edu/clergysexualmisconduct/). She argues that most of the studies regarding this issue have focused on the motives of the offender, the nature of the abusive relationship, and the long-term consequences for both primary and secondary victims. Prevention strategies are rarely considered. Scarce too is information on the steps to follow if you are a victim of clergical sexual misconduct. Garland argues that it is erroneous to consider a sexual relationship 'an affaire' when it occurs between a member of the clergy and a congregational member, and that such relationships are rightfully viewed as clerical sexual misconduct. Providing a proper code of ethics in a congregational context is imperative. Both clergy and

parishioners need to understand that clerical sexual misconduct is inappropriate.

In a national random survey conducted in 2008 with 3558 respondents, Garland and colleagues found that approximately three percent of women who had attended a congregation in the preceding month reported that they had been the object of some form of clerical sexual misconduct in their adult lives. The overwhelming majority of the sexual advances (92%) were made in secret rather than in open dating relationships, and most of the offenders (67%) were married to someone else at the time of the advance. Representing a variety of different Christian and Jewish affiliations, 8% of those surveyed reported having known about clerical sexual misconduct occurring in a congregation they had attended. One of the very important points Garland and colleagues (Chaves and Garland, 2009; Garland, 2009) raised in their work, is the high level of self-disclosure that can occur in congregational life. Garland refers to this as 'trust in the sanctuary' – meaning that congregations are considered sanctuaries, literally safe places, where a person's normal attentiveness to self-preservation need not be a priority. With limited oversight of pastors' work and behavior, clerical sexual misconduct can develop and flourish. Vigilance is necessary both by religious leaders and those who faithfully support them through participation in congregational life.

Abstract

Religious factors have played a considerable role in economic systems throughout history. Here, the relationship between religion and economic systems are examined beginning with the archaic mode of production and continuing through feudalism, early capitalism, late capitalism, and in the present global economy. Marxist and Weberian theories of religion and economic life are presented, along with more modern theories of the complex connection between religion and economics.

Investigation of the relation between religion and economic life has long been a central concern of sociological reflection, but the topic has been largely defined through debates on the relationship of religion and capitalism, the latter being the specific and dominant expression of economic life in modernity. Marxist and Weberian perspectives on religion and capitalism inevitably overshadow the discussion of both the history and the contemporary forms of the ambiguous and changing relation between religion and economic life. First, this article will review precapitalist configurations of religion and economic life. Second, the emergence of modern capitalism is considered. Third, reflective religious responses to nineteenth- and twentieth-century capitalism are outlined. Fourth, the impact of religion on economic life and economic life on religion is examined under contemporary capitalism, which brought with it globalization, commodification, and managerialism, and a wide range of contrasting religious responses. In the concluding section, future avenues for research are considered.

Precapitalist Configurations of Religion and Economic Life

The relationship between religion to economic life depends on the theoretical assumptions of the inquirer. The most relevant founding fathers of sociology, Marx, Weber, and Simmel, sought to develop grand theory. In general terms, sociologists of religion have devised and reinforced relatively homogenous accounts of the modernization process and attendant phenomena of secularization, and they have used particular economic theories in order to inform and justify their approaches. By contrast, under the influence of Marcel Mauss' account of the gift and using exchange theory (Gregory, 1994), anthropologists have generally paid more attention to specific human ecologies and reciprocal community economies as originating in "Stone Age Economics" (Sahlins, 1974). Some anthropologists have correspondingly defended distinctive and reciprocal human ecologies and cultures against the ravages of economic modernization in ways contrary to orthodox sociologists.

Archeological and textual records indicate that ancient Egypt, Assyria, Babylon, and Israel all had contextually relevant, practical financial institutions, but there has been limited attention to how religious institutions factored into the economic operations of archaic empires. The history of Western economic thought is normally traced back to the agrarian world of the fourth- and fifth-century BC, which had a well-defined merchant class. The representative unit of the economy was the household and commodities were exchanged in free markets. In the Graeco-Roman world early 'economic' reflection was based on the *nomos* or law and rule of the household *oikos*, and the practical wisdom of household management (*oeconomicos*) was the source from which early economic conceptions were derived. In the setting of the city-state (*polis*), the universal existence of slavery ensured that labor was relatively fixed and immobile. Religion and economic life as part of the cultural superstructure were conditioned by the dependence of ancient Greek and Roman life upon a slave economy; correspondingly, manual labor was regarded as menial. This classical tradition provided some of the core values of Western culture for two millennia in the West.

Central to Greek thought were the good life and reflection on the nature of virtue: seen thus, economic activity amounted to a mere external factor. Plato and Aristotle were, however, aware of such concepts as the distinction between use value and exchange value, the role of money, and the division of labor. In *The Republic*, the latter corresponded with the human types of ruler, soldier, and worker, and each class pursued its proper, specialized goals. The ideal rulers, the philosopher kings, would ostensibly be free from vulgarity of wealth. In the classical tradition, arts of commerce and the practice of usury were condemned, above all the latter, which makes gain out of money itself and not from the natural object. Money was to be understood as a medium of exchange, a unit of account, and a store of value, but in itself money was barren, and usury the oppressive exploitation of misfortune. The classical Christian doctrine of the Trinity, couched in terms of the 'economy' of God's self-revelation of his 'essential' being, employed a metaphor with an enduring importance. Later, the evolving theology of the atonement repeatedly exploited certain economic metaphors, not least in the conceptuality of payment of debt and redemption from sin.

In prefeudal societies throughout the world, religious institutions were undifferentiated from the state and from economic institutions, yet systematic studies of the influence of

religious institutions on economic life in pre-Christian and non-Christian societies are lacking. Economies based upon slavery were questioned in principle by early Christianity (and probably in other traditions as well), but the slave–master system of the archaic economy was generally supported in all major religious traditions, providing political legitimacy for economic relations in a system where religion, the state, and the economy were intimately intertwined. According to Schumpeter there was little substantial interest in Western Christianity in what was to become the dismal science of economics, for "the Christian Church did not aim at social reform in any sense other than that of moral reform of individual behavior," nor, moreover, "did the Church attempt a frontal attack on the existing social system or on any of its more important institutions." Indeed, "It never promised economic paradise or, for that matter, any paradise this side of the grave" (Schumpeter, 1954: p. 72). Michael Mann argued that "Christianity was a form of ideological power …. Only by becoming a Christian could one live a truly meaningful life" and that its "…power resides originally in the fit between the Christian message and the motivations and needs of the converted" (Mann, 1986: p. 302). The question as to the 'fit' or affinity, between individual Christian belief and spirituality upon individual motivation and economic life has remained a matter of central importance in Weberian scholarship. In contrast, Marxist analysis implied that the religious ideology that emerged in the theological debates of the patristic theologians of the first four centuries in the West was but a reflex of the material base; this, however, does less than adequate justice to the complexity of the factors involved.

After the fading of the eschatological expectation of the earliest Christian communities and abandonment of the primitive communism, monasticism preserved the radical exemplar of the economic ethic of the Synoptic Gospels (Troeltsch, 1931). The religious orders that emerged from the practice of the Desert Fathers provided both the basis for the continuity of a religious culture and an economic model compatible in key respects with the warrior culture of feudalism. Monastic communities and the religious orders came to be centers of rational economic organization in ways that prefigure the business corporation. Monastic organization created wealth, which, in turn, led to inner contradictions tackled by attempts at institutional reform – and which later became the target of acquisitive envy during the Protestant Reformation.

At the high point of scholastic theology and in the context of feudalism, a crucial debate took place, which connects the early economic ideas of Aristotle (and of his wide philosophical concerns) with the early modern loosening of the constraints upon economic activity that facilitated the growth of international trade, and the justification of such expansion in mercantilism. In the Middle Ages, Europe was characterized by a relatively stable agrarian, largely subsistence economy with slow urban growth. Central to urban productive activity was the guild, a form of association, which ensured corporate monopolies, the protection of members, standards of quality, and price stability. A similar form of urban economic organization prevailed in the Islamic world (Kuran, 2011). The presence of the Church in relation to all social institutions ensured an unparalleled degree of cultural interfusion between religion and economic life. Social status and social function implied definite religious duties in a divinely ordered governance that extended throughout the body politic. Nineteenth century guild socialism attempted to recover something of this integration of meaning into 'menial' work.

St Thomas Aquinas, the leading theologian of scholasticism, defended the just price and the prohibition of usury, the core principles of the attempted control by the Church of economic life. Estimating the just price based on moderate gain was a difficult task: the merchant was justified in trading at a price, which ensured the life of his household in its accustomed style. Following Aristotle's account of money as barren, St Thomas condemned usury, the lending of money at interest, arguing that given the true role of money solely as a medium of exchange, it did not exist in the way that a rented house continued to exist when occupied by a tenant. St Thomas' counterrealist account of money applied more to the ethics of the personal loan rather than to large-scale financial transactions. During the course of the fourteenth and fifteenth centuries the increasing complexity of major financial transactions made it increasingly difficult to fit new practices within the constraints of Church law and this was reflected in modifications of St Thomas' rigorist views.

The prohibition of usury was circumvented through the creation of an international system identified with the Jews that was capable of supporting the accumulation of the major loans required for effective warfare. A similar role was also undertaken for a limited period by the Templars. The pariah status of Jews and their indispensable role in facilitating financial transactions and more widely in commerce came to reinforce negative attitudes, which provided a long-enduring basis for anti-Semitism (Stern, 1977: Chap. 18). The role of such Jewish thinkers as Marx and Sombart in the theorization of capitalism in the nineteenth century and beyond reinforced the impression that Jews played an essential role in the development of modern capitalism (Paul Morris in Roberts, 1995: Chap. 5). In contrast to the shifting perspectives on finance and usury in the Christianity, Islamic empires remained committed to prohibitions, and allowed Christians and Jews to have advantageous access to developing mercantile (Choudhury and Malik, 1992; Kuran, 2011).

In the early modern period, the growth of international trade, the breakdown of unity within Christendom following the Reformation, and the destruction of stable communities unified by shared religious values were factors associated with the rise of mercantilism. During the course of the sixteenth, seventeenth, and eighteenth centuries, economic analysis gradually gained increasing autonomy, throwing off the remaining constraints of scholasticism in favor of market-based mercantilism and physiocratic economic theories.

The Emergence of Modern Capitalism and Its Critique

The advent of early industrialization and the development of the factory system brought about unprecedented social disruption, breaking many ancestral ties: this process required both explanation and legitimation. In *The Wealth of Nations* (1776), Adam Smith articulated a world view in which virtue is equated with profit. Smith's analysis of the rational division of

labor and its necessary place in the making of profit provided the justification for the removal of remaining constraints. The quasi-providential 'invisible hand' purportedly provided a spontaneous connection between individual wealth creation and the common good of society. Political economy attained a high status among an ascendant entrepreneurial class as it emancipated economic practice and provided the means for the elimination of embedded social, ethical, and cultural inhibitions, including those traditionally endorsed by religion in preindustrial agrarian societies.

Marx regarded the intellectual destruction of religion by the eighteenth century Enlightenment as the axiom underpinning the true emancipation of humankind through subsequent social, political, and economic critique, and for Marx there was no basis for any mutual reflective encounter between religion and economic life. The representation of the proletariat in Marxist theory crystallized the fears of churches already confronted with their loss of influence over a growing urban working class and its anticlericalism.

The uprooting of agrarian workers from an ancestral status sanctioned by divine order and their regimentation into a disciplined, wage-earning working class differentiated by a new division of labor created a dilemma for the churches. On the one hand, the Anglican clergyman Thomas Malthus endorsed population regulation in accordance with economic needs. On the other, the living conditions of the working class were an affront to those sensitive to the historic Christian teaching on wealth and poverty. Such figures as the Scot, Thomas Chalmers, English Christian socialists, and continental religious socialists struggled to find ways to redefine the role of religion under industrialized conditions. An unchurched, brutalized proletariat represented a threat to the role of Christian clerical and intellectual elites across Europe. In the English religious establishment, serious critical engagement with 'scientific socialism' or political economy was minimal. Methodism was exceptional in that it successfully harnessed religion and industrial work in ways, which may have spared England a revolution.

Max Weber was fully aware of the threat, which Marx's thought and Marxist socialism created for Liberal Protestant European bourgeois culture and society. According to Weber, the *mentalité* associated with the capitalist mode of production had historical connections and elective affinities with 'this-worldly' Protestant asceticism. It is therefore customary (but not undisputed) to link the nascent 'spirit of capitalism' with the much disputed 'Protestant ethic' particularly in the Reformed Christian tradition. Weber explored the affinities between the single-minded pursuit of God and an equally focused desire for profit, but he also applied his analysis to the major world religions, classically, for example, to the religion of India (D. Gellner in Roberts, 1995: Chap. 1). Marx and Weber agreed on the centrality of acquisitiveness to the bourgeois mind: political economy both explained and justified single-minded acquisitiveness, and divorced economic relations from human needs. In fact the greatest good of this ethic, the earning of more and more money combined with strict avoidance of all spontaneous enjoyment of life, ignores the production of happiness as a measure of the merits of an economic system. Economic acquisition is no longer subordinated to man as the means for the satisfaction of his material needs (Weber, 1930/1976: p. 53).

In *Religion and the Rise of Capitalism*, R.H. Tawney applied Weber's insights to seventeenth-century England, and provided an indirect critique of the *laissez-faire* liberal capitalism, which underwent economic and social crisis during the period between World War I and World War II. Later, further British explorations of the processual metaphor of the 'rise' of capitalism were extended by V.A. Demant to its 'decline' and its 'persistence' by R.H. Preston. Christian thinkers such as the Anglican William Temple relied upon the emerging Keynesian standpoint in advocating 'middle axioms' as the basis for socioethical intervention. Following the World War II, the Keynesian program of partly state-managed mixed economy (and declining) capitalism underpinned the ideology and implementation of the 'welfare state' for 30 years until the 'triumph of capitalism' associated with the Reagan–Thatcher era. The reassertion of neoclassical economics (Friedman, 1962) and the ideology of the New Christian Right (Green, 1987) stripped away both tacit belief in the 'hidden hand' and all ascetic hesitance with regard to hedonism (Roberts, 1992). Mainline religions in Anglo-American Western countries were split between localized variants of the 'option for the poor' and outright endorsement of the 'enterprise culture.' Those who advocated the option for the poor were depicted as naive and ill-informed practitioners of the 'kindness that kills.' Conversely, New Christian Right ideologues proclaimed the virtues of greed, the adequacy of the 'trickle down' theory of welfare, and the necessity of a docile, 'flexible' labor force willing to be uprooted and exploited.

Reflective Religious Critiques of the Relation of Religion and Economic Life

The most significant mainline religious response to industrialization and to the growth of capitalism and Marxist socialism is to be found in Roman Catholic social teaching. After lengthy consultation provoked by the changing socioeconomic conditions of the nineteenth century, the papal encyclical *Rerum Novarum* was published in 1891. Aware of the fate of the Catholic Church in revolutionary France (and then later of the Orthodox Church in Soviet Russia), papal teaching represented the historic struggle between capital and labor as conflict between the competing rights and obligations of owners and of workers, in relation to which the Church was to exercise a moderating role. Both parties were to recognize the mutuality of their rights and obligations, and to relativize these through acknowledgment of the beatific vision as the sole and legitimate goal of humankind. For a century, the Church developed this doctrine through a series of encyclicals culminating in Pope John Paul II's *Laborem exercens* (*On Human Work*) (1981). Following the collapse of Marxist socialist states in 1989/90 the changing nature of capitalism was recognized in the encyclical *Centesimus Annus* (1991). The latter contains a cultural rather than a politico-legal analysis and critique of both socialism and capitalism in which the integrity of the human agent is asserted against the contradictions of a destructive, secularizing modernity in need of comprehensive reevangelization. This tradition of Catholic opposition to inequality and support for the lower classes is strongly ascendant in the pronouncements of Pope Francis.

Direct intellectual contact between Christians and Marxist socialists did not take place on a significant scale until after the Second Vatican Council (1962–65) and took the form of Christian–Marxist dialogue during the following decade, but even this discussion of the nature of 'true humanism' would seem to have had minimal long-term influence. At the same time 'political theology' embodying a synthesis between Protestant theology and various strands of revisionist Marxism also developed in Germany. Insights from political theology were transplanted to Central and Latin America, where, after the Second Vatican Council and the Medellin Bishops' Conference of 1968, 'liberation theology' emerged in the context of rapid industrialization and urbanization. This theology drew critical perspectives from Marxist analysis of society but side-stepped the atheistic aspects of Marxism, as was to be emphasized in the critical response of the Sacred Congregation in Rome. In Central and Latin America liberation theology's stress upon the 'option for the poor' has tended to exacerbate a divergence between Roman Catholicism and Pentecostal Protestantism, where the latter has performed a role analogous to that of Methodism during the European industrial revolution (Martin, 1990: pp. 27ff.). The most radical theological critique of capitalism through the representation of the imbalanced distribution of wealth in the global economy was a confessional issue (Duchrow, 1987).

The Roman Catholic apologist and critic of liberation theology Michael Novak has written of a 'magic capitalism.' Humankind has to abandon the naive and infantile 'dream' (the 'false consciousness') of socialism, and to recognize the universal necessity of alienation at the heart of a vital economic reality. Every individual must pass through a rite of passage in which each encounters the 'empty shrine' of 'democratic capitalism': this is the contemporary "dark night of the soul" (Novak, 1982/1991: p. 53). Others, like Peter Berger, deny that capitalism has such mythicizing power (Berger, 1987). Additional accounts of religion and economic life are to be found in Protestant Christian theologies of 'God' the Economist (Meeks, 1989).

Recently, the globally influential 'Third Way' politics of the center left advocated by some has been accompanied by a revival in Christian socialism and continuing campaigns to remoralize the individual. This post-Keynesian and post-communist active capitalism seeks to combine the ideology of entrepreneurial zeal with managerialism and relentless socio-cultural 'modernization.' The 'Third Way' contributes to the increasing salience of the religious factor in economic life, albeit with paradoxical consequences.

Contemporary Capitalism: Globalization, Commodification, and Managerialism

Contemporary capitalism has diversified into a plurality of capitalisms, each with its contextually relevant elective cultural affinities between religion and economic life. These capitalisms have become consolidated through globalization into an infinitely complex system. The representation of globalization as a new paradigm for the sociological interpretation of religion (Robertson, 1992) has encouraged investigation of the struggle both between and within religions for power and influence in the context of the asymmetrically distributed economic opportunities and outcomes in an ever more competitive core–periphery world system (Beyer, 1995). Moreover, the problematic interface between the global and the local has become the focal point of social identity formation (Castells, 1996: vol. II, Chap. 1). Commodification, the ascription of exchange and monetary value to all aspects of the world and human life, has advanced inexorably with the result that the economic function is central, and natural or intrinsic values become ever more marginal and are reduced to mere market values. Global managerialism (Entemann, 1994), mediatized marketing techniques, and the application of 'neo-Fordist' organization to manage work (Drucker, 1993) have accelerated the homogenization of human beings through the replacement of critical education with rational training. These are now processes replicated within some influential strands of both mainline religion and alternative spiritualities.

Information technology has increased the velocity of circulation of all forms of 'capital' to the point that space–time compression is having pervasive cultural consequences in new 'economies of signs and space' (Lash and Urry, 1994). For those at the heart of a core–periphery economic system, capitalism has become 'soft' and infused with transformative cultural power (Thrift, 1997). Under these conditions, religious language and theological vocabulary have become resources for the expression of economic and cultural power. Thus, terms like 'omnipresence,' 'omnipotence,' 'omniscience,' and 'instantaneity' formerly attributed to the 'God' who subsisted at the core of Western consciousness are perhaps the only adequate conceptual categories for such transmutations. Spiritual practices are now recruited into management training in order to assist through the provision of peak experiences the strongest possible integration of individual motivation with corporate goals (Roberts in Roberts, 1995: Chap. 9). The religious field may be remapped in relation to these ongoing transformations of economic life. The application of rational choice theory to religious behavior, a syncretic global marketplace of New Age 'self-religions' and spiritual body practices, the managerialization and marketization of mainline Christianity, Christian fundamentalist 'prosperity theology,' neo-pagan 'nature religion,' and ecological piety are all indications that religion and economic life are in active and sometimes mutually contradictory synergies. Consequently, there is no one 'spirit of capitalism' in advanced modernity – but a multiplicity of affinities and collusions in context marked by growing differentiation between 'religion' and 'spirituality.'

Conclusion: Future Prospect – Research Options

In the modern world, the modern and the postmodern conditions sometimes coexist in close, yet problematic contiguity (Harvey, 1989). From being marginal to the order of things, conscious economic rationality is now for many 'life' itself. 'Economic life' tends to absorb, transmute, and meld 'reality' into a globalized *maya*, outside of which there would appear to be no fulcrum for a critical ideology or politics of resistance (Baudrillard, 1981). After the so-called 'End of History,' leading sociologists of religion such as Steven Bruce and Bryan Wilson continue to represent religion as subject to terminal attrition by an inevitable process of secularization.

Regarded thus, religion can no longer be a resource for the culturally significant critique of total human submission to the dictates of 'economic life.' Yet, this view of the role of religion in economic life ignores the resurgence of religious control over economies in most of the middle east, and the overarching political power of conservative Christianity in the United States and Russia, the rising dominance of conservative Hindu nationalism in India, pan-Islamic movements throughout Asia, and Buddhist control over the political economy of Sri Lanka and much of Southeast Asia.

Future research could productively focus on the intersection between modern religious movements throughout the world and their impact on economic relations. The political economy of the contemporary world is dominated by the impact of mass political movements, which regulate economies, determine the fortunes of individuals and groups, and fuel economically devastating wars. Religious movements will also play a substantial role in determining responses to global climate change, and it is unclear how different religious movements will respond. For example, conservative Christian movements in the United States have played a key role in deregulating the economy and denying that human activities have consequences for the environment and climate. And, it appears that Hindu nationalism is playing a similar role in India. Religious movements are also responsible for undermining the economic fortunes of women, denying them access to education, health care, transportation, and basic freedoms – with considerable negative economic consequences for nations and for the global economy.

Abstract

This article provides a brief review of research on religion and health and suggested clinical applications. Most of the research reviewed was published between 1960 and 2010 and is based on a systematic review, although more selected recent research has also been included. The majority of the research summarized here indicates that religious involvement is related to better mental health, social health, health behaviors, and physical health overall. We examine here why this might be the case, and then make recommendations on what health professionals should do differently based on these research findings.

Religion and health have been of considerable interest to humans throughout recorded history, although until recently the relationship between the two had not been carefully examined through scientific research. This has changed in the past 25 years, as increasing attention has been paid to the connections between religion and health by psychological, social, behavioral, and medical researchers. Most of the world's population's religious beliefs are often central to how the people view life, and in particular, how they make sense of trauma, loss, and physical illness.

Based on an international survey of 51 927 persons from 57 countries, only 13% of the world's population are atheists, and most of these individuals are concentrated in China (47% atheist) and Japan (31% atheist) (WIN-Gallup International, 2012). Furthermore, only 23% of the world's population are not religious (again, most are concentrated in East Asia). Hindus are most likely to say they are religious (82%) compared to Christians (81%), Muslims (74%), and Jews (38%). Religiosity is highest among the poor (66% of those in the lowest quintile of income) and uneducated (68% of those with less than a secondary education).

The most religious of the 57 countries surveyed were Ghana, Nigeria, Armenia, Fiji, and Macedonia (all over 90%). The least religious were Sweden, Turkey, the Czech Republic, Japan, and China (under 30%). In Turkey (a Muslim country), only 23% described themselves as religious. In the Czech Republic (a Christian country, but until recently Communist), only 20% described themselves as religious. Globally, there was a 9% decline in religiosity from 2005 to 2012. During this time, the countries showing the greatest decline in religiosity were Vietnam (−23%), Switzerland (−21%), France (−21%), South Africa (−19%), and Iceland (−17%). Countries showing an increase in religiosity were Pakistan (6%), Macedonia (5%), Moldova (5%), Serbia (5%), and Malaysia (4%). Interestingly, those *under age* 30 and over age 65 were most likely to describe themselves as religious (60% and 66%, respectively).

What Is Religion?

According to the definition provided in the *Handbook of Religion and Health*, "[Religion] Involves beliefs, practices, and rituals related to the *transcendent*, where the transcendent is God, Allah, HaShem, or a Higher Power in Western religious traditions, or to Brahman, manifestations of Brahman, Buddha, Dao, or ultimate truth/reality in Eastern traditions. This often involves the mystical or supernatural. Religions usually have specific beliefs about life after death and rules about conduct within a social group. Religion is a multi-dimensional construct that includes beliefs, behaviors, rituals, and ceremonies that may be held or practiced in private or public settings, but are in some way derived from established traditions that developed over time within a community. Religion is also an organized system of beliefs, practices, and symbols designed (a) to facilitate closeness to the transcendent, and (b) to foster an understanding of one's relationship and responsibility to others in living together in a community"(Koenig et al., 2012: p. 45). Religion is distinguished from the term "spirituality," which is now understood as a broader concept than religion (although may suffer from measurement contamination when conducting research) (Koenig, 2008).

Is Religion Related to Health?

We examine the research findings related to religion/spirituality (R/S) and health in four sections: mental health, social health, behavioral health, and physical health. This summary is based on a systematic review of peer-reviewed quantitative, original research reports published largely from 1960 through mid-2010. This research is described in more detail in the two editions of the *Handbook of Religion and Health* (Koenig et al., 2001, 2012).

Besides summarizing the research findings, the Handbooks also provide quality ratings for each of the approximately 3300 studies. These quality ratings range from 0 (low) to 10 (high) and are based on six criteria: study design, sampling method, number of R/S measures, quality of measures (both religious predictors and health outcomes), inclusion of control variables, and statistical method. We summarize the research findings below in terms of the total number of studies and of the studies with quality ratings of 7 or higher.

Mental Health

Most of the research on religion and health (80%) focuses on mental health. Of primary importance is that religion is often

used to cope with difficult life circumstances out of the individual's control. We identified 454 such studies that explored the role that R/S played in helping people cope with conditions as diverse as general medical illness, chronic pain, renal disease, diabetes, lung disease, malignancy, disorders of the blood, heart and other cardiovascular diseases, vision and dental problems, neurological syndromes, acquired immunodeficiency syndrome, systemic lupus erythematosus, inflammatory bowel disease, musculoskeletal disease, caregiver burden, chronic psychiatric illness, loss of loved ones, conditions at the end-of-life, natural disasters, war, acts of terrorism, and a wide range of other challenging traumatic events and difficult circumstances. In most of these studies, people reported that R/S was helpful in coping. In some studies of medically ill adults, 90% said religion enabled them to cope at least to a moderate degree and over 40% said it was the most important factor that kept them going.

Mental Disorders

By improving coping, R/S beliefs and practices could influence the development and course of common mental disorders, including depression, suicide, anxiety, psychosis, and substance use disorders.

Depression

At least 444 studies had examined the relationship between R/S and depression prior to mid-2010. Among those, 272 (61%) reported significant inverse relationships between R/S and depression (including nine studies at a statistical trend level) and 28 (6%) reported greater depression in those with more belief in R/S (2 studies at a statistical trend level). Of the 178 studies rated at 7 or higher on quality, 119 (67%) reported inverse relationships and 13 (7%) positive relationships (i.e., greater depression among those who were more religious). At least 30 clinical trials examined the effects of an R/S intervention on depression compared with either standard treatment or a control group. Of those, 19 (63%) reported a significant decline in depressive symptoms in response to R/S interventions compared to controls, whereas 2 studies (7%) found standard treatments superior to R/S interventions.

More recently, psychiatric epidemiologists at Columbia University have published a series of reports on a cohort of children at low or high risk for depression because of parents with depressive disorder. These studies have found that religious involvement may prevent the development of depression in high-risk persons (Miller et al., 2012, 2014; Kasen et al., 2012).

Suicide

The research above is consistent with three-quarters of published research on R/S and suicide attempts, completed suicide, or attitudes toward suicide, which find lower risk among those who are more R/S. Of 141 studies, 106 (75%) have found inverse relationships with R/S, whereas 4 (3%) have reported positive relationships. As the methodological rigor of the studies improves, the likelihood of finding inverse relationships increases from 75% to 80% (i.e., 39 of 49 studies).

Anxiety

Our review identified 299 studies that had examined relationships between R/S and anxiety, of which 147 (49%) found inverse associations with R/S (three at a trend level) and 33 (11%) found greater anxiety. Most of the latter (94%), however, were cross-sectional studies, making it impossible to determine whether R/S was the cause of the greater anxiety or whether great anxiety was the cause for R/S involvement. Quality of the study did not seem to influence the findings. Fifty-five percent (38 of 67 studies with quality ratings of 7 or higher) reported inverse relationships, while 10% (7 of 10) reported greater anxiety among the more R/S. Included here were 32 randomized clinical trials, of which 22 (69%) found that R/S interventions were more effective in reducing anxiety than standard treatment or control conditions (only one study reporting worse outcomes in the R/S intervention group and that was among individuals suffering from severe alcohol dependence).

Psychosis

Relationships with psychosis are less clear. Only about one-third (14 of 43) of studies have found inverse relationships between R/S and psychotic symptoms, whereas one-quarter (10 of 43) of studies have reported positive relationships. Two studies that reported inverse relationships between R/S and psychosis were prospective in nature, where those who had more belief in R/S had better outcomes. The reader is referred elsewhere for a more comprehensive discussion of R/S and psychotic disorders (and ways that clinicians can distinguish the two) (Koenig, 2011).

Alcohol and Drug Use/Abuse

While the relationship between R/S and psychotic symptoms may be somewhat unclear, there is no doubt about associations with alcohol and drug use. Of the 278 studies that examined relationships between alcohol use/abuse and R/S, 240 (86%) have found inverse relationships, whereas only 4 studies reported a positive relationship. Studies with the best methodology report the same findings (i.e., 90% of 145 studies with quality ratings of 7 or higher report inverse relationships with R/S). Relationships between R/S and drug use/abuse are similar. Of 185 studies, 84% have found inverse relationships, whereas only 2 studies reported positive relationships. Again, the findings were not influenced by the quality of the study. Note that most of these studies were conducted on high school and college students, which are a particularly vulnerable group and this is the time when youth are beginning to establish substance use patterns that will influence the rest of their lives.

Positive Emotions

Although of less interest to clinicians, the experience of positive emotions is of considerable importance to individuals in the general population, who may be quite concerned about the relationship between R/S involvement and emotional states such as well-being, happiness, optimism, hope, meaning and purpose, and self-esteem, which often make life worth living (or not).

Well-being

Among the 326 studies that examined relationships between R/S and well-being, happiness, or life satisfaction up through mid-2010, nearly 80% (256 studies) reported significant positive relationships (eight at a statistical trend), compared to <1% that found inverse relationships. Again, quality of the study had little effect on the findings, such that 82% of the 98 best studies reported positive relationships and only one study reported a negative relationship.

Hope

The majority of studies found that R/S individuals are more hopeful. Among the 40 studies we identified in our systematic review, 29 (73%) reported significant positive relationships and no studies found inverse relationships.

Optimism

Of the 32 studies examining relationships between R/S and optimism, 26 (81%) reported significant positive relationships and no studies reported inverse relationships.

Meaning and Purpose

Sigmund Freud said that "…only religion can answer the question of the purpose of life. One can hardly be wrong in concluding that the idea of life having a purpose stands and falls with the religious system" (Freud, 1930). On this point Freud was probably right. Of the 45 studies that have examined relationships with R/S, 42 (93%) reported significant positive relationships, and of the 10 studies with quality ratings of 7 or higher, all (100%) reported significant positive associations.

Self-esteem

Although psychiatrists have argued that R/S may adversely affect self-esteem because it fosters humility and discourages pride (Watters, 1992), the research published to date does not support this claim. Of the 69 studies that have examined relationships with self-esteem, 42 (61%) have reported *greater* self-esteem among the more R/S and only two studies have found lower self-esteem. As the quality of the study increases, the results remain favorable toward R/S, where 17 of 25 (68%) reported greater self-esteem. These findings are consistent with those reported between R/S and depression or suicide, which often result from a loss of self-esteem.

Social Health

Social health involves social support, marital stability, absence of crime and delinquent activities, altruistic activities, and social capital. R/S is related to every one of these, and the direction of those relationships is consistent.

Social Support

We identified 74 studies examining associations between R/S and social support, including a number of social contacts, frequency of interaction with family and friends, and subjective sense of satisfaction with that support. Of those studies 61 (82%) found that R/S was associated with significantly higher social support, and none found lower social support. Nearly all of the highest quality studies (27 of 29) found greater social support among the more religious. This is especially true for older adults in whom members of the faith community are often the most important source of support outside of family members (Cutler, 1976; Koenig et al., 1988).

Marital Stability

Of the 79 studies we identified up through mid-2010, 68 (86%) reported significant relationships between R/S and lower rates of divorce, higher rates of two-parent homes, greater marital satisfaction, and lower rates of spousal abuse. Among studies with the best methodology (ratings of 7 or higher), 35 of 38 studies reported this finding. These results are consistent with meta-analytic reviews of the literature by others (Mahoney et al., 2001) and by more recent research published in this field (Spilman et al., 2013; David and Staffor, 2013).

Delinquency/Crime

Of the 104 studies that examined relationships with R/S, again the vast majority (79% or 82 or 104) found inverse relationships with delinquency during youth and crime during adulthood. Only three studies have reported the opposite. Of the 60 methodologically most rigorous studies, the same proportion (82% or 49 of 60 studies) found less delinquency and crime among the more religious.

Altruistic Activities

Our systematic review of R/S and altruism/volunteerism found that 70% (33 of 47 studies) reported significant positive relationships, and if organ donation studies are excluded (since some religions prohibit this practice), the percentage of positive studies increases to 79%.

Social Capital

Social capital is a term used to describe the overall health of a community, and is often assessed by measuring level of community participation, trust, reciprocity between community members, rates of volunteerism, and proportion of the community that participates in civic, political, or social justice organizations. Again, the vast majority of these studies (79% or 11 of 14 studies) reported that R/S of members in a community relates to significantly greater levels of social capital.

Behavioral Health

Religious beliefs and doctrines may influence lifestyle choices related to physical health by emphasizing responsibility to care for and nourish the body (while avoiding gluttony). Behaviors that harm the body are discouraged, since good health enables the religious person to serve God and others. We review here studies that have examined relationships

between R/S and cigarette smoking, exercise, weight, diet, and sexual behavior.

Cigarette Smoking

At least 137 studies that examined the relationship with cigarette smoking, and of those, 90% (123 studies) reported that R/S is related to significantly less cigarette smoking (three at a trend level). No studies found positive relationships with smoking. Likewise 75 of the 83 highest quality studies reported this finding. Many of these were among youth. Consider the effects that this single health behavior is likely to have, given the fact that cigarette smoking is associated with 30% of all cancers, chronic lung disease, and increased rates of coronary artery disease, hypertension, and stroke later in life.

Exercise

In general, those who are more R/S also tend to be more physically active. We found that two-thirds of studies (25 of 37) examining this relationship found higher rates of exercise or greater physical activity among the more R/S, compared to six studies (16%) that found less activity. Of the 21 best studies, 16 (76%) reported positive associations and 2 (10%) found negative associations.

Weight

Unfortunately, greater exercise and less cigarette smoking do not translate into lower weight among the religious. Of all the health characteristics, this one tends to be problematic among the religious. We identified 36 studies that examined the relationship between weight (body mass index) and R/S involvement, of which 14 (39%) found that religiosity was related to *greater* weight, whereas only 7 studies reported lower weight (19%). The findings do not change among the higher quality studies (44% greater weight, 20% lower weight). Eating seems to be the one sin that is not only allowed but encouraged in faith community settings. The Amish, Jews, and Buddhists tend to have lower weight than Christians and Muslims.

Diet

Although weight is a problem, at least the composition of food intake on average tends to be better among the more R/S. Of the 21 studies that have examined relationships with diet, R/S were more likely (62% of studies) to have increased intake of fiber, green vegetables, fruit, and fish; low intake of snacks, processed foods, and fat; regular vitamin intake; frequent eating of breakfast; or overall better nutrition. Among the highest quality studies, 7 of 10 found a better diet among the more religious. Cholesterol levels also tend to be lower. Of the 23 studies that examined this relationship, 12 found lower cholesterol levels among the more R/S, whereas 3 found higher cholesterol.

Sexual Behavior

Given the relationship between extra-marital sexual activity and a host of sexually transmitted diseases, this is another behavior likely to influence health status and susceptibility to disease (syphilis, gonorrhea, herpes, chancroid, chlamydia, viral hepatitis, human papillomavirus, human immunodeficiency virus, etc.). Of the 95 studies that examined relationships between R/S and sex outside of marriage (premarital, extra-marital, number of partners, etc.), 82 (86%) found lower and 1 study (1%) found higher rates of risky sexual activity among the more R/S. Among the 50 highest quality studies, the findings were similar (84% inverse relationships, 0% positive relationships).

Physical Health

Given the well-known relationships between physical health and mental, social, and behavioral factors, a relationship between R/S and physical health would be expected. Such relationships, however, are often – if not always – indirect and act through psychosocial–behavioral pathways. Here we examine the relationships between R/S and coronary heart disease (CHD), blood pressure (BP)/hypertension, cerebrovascular disease, dementia, immune and endocrine functions, cancer, and overall mortality.

Heart Disease

Psychosocial and behavioral factors are known to influence the development and course of CHD. We would expect R/S involvement to do likewise. We identified 19 studies that had examined associations between R/S and CHD up through 2010. Nearly two-thirds (12 studies or 63%) indicated lower rates among those who were more R/S, whereas one study found a significant positive association. Similarly, nine of the 13 most rigorously designed studies (69%) reported less CHD among the more R/S. This research is supported by studies examining relationships between R/S and a wide range of cardiovascular functions or outcomes, including cardiovascular reactivity, heart rate variability, cardiac surgery outcomes, and other vascular functions. Eleven of 16 such studies found positive relationships between R/S and these functions or inverse relationships with inflammatory markers (C-reactive protein) or coagulation factors (fibrinogen) that increase the risk of vascular disease.

Hypertension

Our systematic review identified 63 studies examining associations between R/S and BP or rates of hypertension. As expected, the majority (36 studies or 57%) reported inverse relationships, compared to 7 studies (11%) that found significantly higher BP or hypertension. Among the 39 best designed studies, 24 (62%) reported lower BP among those who are more R/S or in response to an R/S intervention.

Cerebrovascular Disease

Since vascular disease and hypertension are strong predictors of stroke and other forms of cerebrovascular disease, R/S involvement should likewise influence these disorders. Of the

nine studies we identified that examined this, four reported a lower risk of stroke among the more R/S, whereas one paradoxically found greater carotid artery thickening (increasing stroke risk) (Feinstein et al., 2010).

Alzheimer's Disease and Dementia

Vascular disease also increases the risk of vascular dementia and the risk of Alzheimer's disease in older adults. Depressive disorder and high stress may also contribute to the development of dementia acting through elevated cortisol levels that adversely affect large neurons in the temporal lobes (Betz cells) of the brain. By reducing vascular disease and emotional stress, R/S might influence the course of memory loss later in life. Furthermore, the higher cortical functions activated as a result of religious beliefs, reading, and thinking about theological issues, may help to preserve these functions. Our systematic review identified 21 studies that examined associations between R/S and cognitive function in older adults. Half of these studies (10 or 48%) found better cognitive functioning in the more R/S and three reported worse cognitive functioning. Higher quality studies, including several that examined these relationships prospectively, were also likely to report such findings (8 of 14 studies or 57%). Recent research has continued to find better cognitive functioning among older adults who are more religious (Coin et al., 2010; Zhang, 2010; Inzelberg et al., 2013).

Immune Function

The immune system is responsible for preventing disease and preserving internal homeostasis. Our systematic review identified 27 studies that examined relationships with R/S. The majority (15 of 27 or 56%) reported positive associations or improved immunity in response to an R/S intervention. Only one study reported an inverse association. Likewise, 10 of the 14 highest quality studies reported better immune function among the more R/S. Better immune function is also reflected in susceptibility to infection. We identified an additional 12 such studies that examined R/S and infection rates or virus concentrations in blood (viral load). Two-thirds (67%) of these studies reported lower infection rates or viral load in those who were more religious, and the higher quality studies reported similar results (70%).

Endocrine Function

Endocrine functions of particular interest here are the stress hormones – cortisol, epinephrine, norepinephrine. Among 31 studies that examined levels of R/S or R/S interventions, 23 (74%) reported inverse associations or positive effects (most studies examining Eastern meditation) on stress hormone levels. No studies reported higher levels of stress hormones in those who are more religious or in response to R/S interventions.

Cancer

Among the 29 studies examining relationships between R/S and the development or course of cancer, 16 (55%) reported lower rates or better prognosis among those who had more belief in R/S, whereas 2 studies reported worse prognosis. Similar findings were reported among the methodologically more rigorous studies (60% better outcomes, none with worse). These findings may be explained in part by better health behaviors (less cigarette smoking, alcohol intake, etc.), although not entirely.

Mortality

If R/S involvement is related to better mental, social, behavioral, and physical health over the lifetime, these effects should manifest themselves in terms of longevity. We identified 121 studies examining the ability of R/S to predict survival (most being prospective cohort studies). Of those, 82 (68%) found greater longevity among the more religious (three at a trend level), whereas 6 studies (5%) found a worse survival rate. Of the 63 best designed studies (largest samples, best R/S measures, longest follow-up), 47 (75%) reported greater survival among the more religious. These findings have been supported by at least three other systematic reviews (McCullough et al., 2000; Powell et al., 2003; Chida et al., 2009). The effect on longevity has been compared to the effect of cholesterol lowering drugs or exercise-based cardiac rehabilitation on survival following myocardial infarction (McCullough, 2001).

How Religion Affects Physical Health

We have already hinted at the mechanisms likely responsible for the effects that R/S has on physical health and longevity. We summarize and integrate these psychosocial, behavioral, and physiological pathways here.

Religious beliefs and behaviors are important in helping people to cope with adversity and life stress, giving meaning to loss and change. This reduces the likelihood of developing stress reactions, depression, anxiety, and resorting to alcohol and drugs for comfort, and increases the likelihood of experiencing positive emotions such as hope, optimism, and well-being, enhancing outlook and self-esteem. Religious involvement also increases social contacts and may enhance the quality of social interactions, since religious doctrines promote the love of neighbor, altruistic acts, and the practice of forgiveness. The psychological and social benefits of religion likely translate into consequences for physical health as well. Physiological changes in immune, endocrine, and cardiovascular functions help to preserve homeostatic mechanisms which help to prevent disease or facilitate recovery. In addition, religious doctrines that discourage behaviors that adversely affect health, such as cigarette smoking, excessive alcohol use, drug use, risky sexual behavior, and encourage those behaviors that preserve health, such as physical activity and attention to diet, have physical health consequences.

There are other pathways by which R/S likely influences health, and by which mental and physical health probably influence R/S belief and activity. There is no doubt genetic and developmental factors influence health and well-being, and there is growing evidence that these factors may influence religious beliefs, practices, and experiences as well (Dew and Koenig, 2014), adding complexity to the religion–health relationship. Personality or temperament (strongly

influenced by genetic factors and early childhood experiences) may help to determine whether a person engages in religious activities, and may also influence psychological, social, and behavioral factors that affect physical health and susceptibility to disease. These factors must be taken into account when examining the religion–health relationship, including the fact that those with the least resources (the poor, uneducated, marginalized minority groups) are often the most religious. As Karl Marx often quoted, religion is the "opiate of the masses" (i.e., those with the most disadvantages).

Clinical Applications

Clinical applications that result from the relationships found here are vast. The primary application at the patient level is that health professionals should be willing to identify and discuss patients' religious or spiritual beliefs with them. This is done primarily by taking a spiritual history from patients with chronic or serious medical or psychiatric illness, and then ensuring that spiritual needs that arise during such discussions are addressed by those trained to do so (typically chaplains or pastoral counselors). Resources now exist that will help guide health professionals in this task (Koenig, 2013).

Summary

Religious beliefs and practices are often used to cope with mental and physical illness. Studies show that those who are more R/S experience better mental health and adapt better to medical illness, stress, and trauma. They also have larger and more supportive social networks, and live healthier lifestyles, avoiding behavior likely to adversely affect their health. These psychological, social, and behavioral influences are also likely to have consequences for physical health, susceptibility to disease, and ultimately on survival and mortality, as the vast majority of research now demonstrates. These relationships with health, along with the widespread presence of spiritual needs during serious or chronic medical illness, have implications for clinical practice. Health professionals should begin to regularly inquire about the religious or spiritual beliefs of patients and be willing to discuss these issues as they relate to the health care being provided.

Religion and Health: Sociological Considerations

Ellen L Idler, Emory University, Atlanta, GA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Empirical studies and theoretical reasoning about religion and health began with the origins of the discipline of sociology. Theoretical frameworks draw on Durkheim's concepts of social integration and regulation to understand religion as a determinant of health, and on Weber's concept of *verstehen* to understand religion as a source of meaning in illness. Physical health measures include mortality, morbidity, and disability; mental health measures include well-being, disorders of depression, substance abuse, anxiety, and psychoses. Multiple explanatory mechanisms for the relationship, including reduced risk behaviors, enhanced social support, and effective coping strategies, have been proposed.

There are two distinct ways in which religion may be related to health. Religions – complicated systems of symbols, beliefs, practices, and the social institutions associated with them – may be considered among the psychosocial factors that have apparent influence on health status. In this view, religiousness may be investigated as a protective or preventive factor in reducing mortality or morbidity. A second view reverses this causal order, as religious beliefs and practices are often turned to by individuals and families faced with serious illness, or at the end of life, and religiousness can be affected by changes in aging or health status. Research approaching religion and health from both perspectives has increased dramatically since the 1980s. The comprehensive Handbook of Religion and Health, first published in 2000, was revised in 2012 (Koenig et al., 2012); the authors estimate that there are over 2800 original data-based quantitative studies of some aspect of religion/spirituality and health or clinical practice now published in peer-reviewed journals.

Religion as a Factor Affecting Health

> The earliest examples of practices designed to promote the public health are to be found, among primitive peoples, inextricably mingled with the ritual of religion.

These are the opening words of C-E. A. Winslow in the entry for 'Public Health' in the original 1935 Encyclopedia of the Social Sciences, an early precursor to the present volume. Winslow, professor of public health at the Yale School of Medicine and known for his studies of the decline in infectious disease mortality, drew attention to early quarantine efforts in ancient Persia and among the Biblical Hebrews as effective public health practices, motivated and given form by religious beliefs. The burial of the dead, the separation of lepers from the community, or the ritualistic preparation of meat for consumption are but a few of the early examples of practices carried out for religious reasons that had unintended public health consequences. In general, this characteristic of being unintended is typical of the work discussed under this heading – religious practices or beliefs seen to have associations with health are not adopted for the purpose of improving individual or community health, but rather, are valued ends in themselves.

The social scientific origins of both theoretical and empirical work on religion and health can be found in Emile Durkheim's (1951) *Suicide*. Durkheim demonstrated, with the use of European national and regional statistical records, that suicide rates varied dramatically and predictably with certain social characteristics, among them the rates of Protestants, Catholics, and Jews in a population. His finding that suicide rates were lower in regions with larger Catholic and Jewish populations led him to denote types of suicides (anomic and egoistic) in modern societies. Suicides were prevented in religious and other social groups that regulated or constrained the behavior of individual members and also provided them with integrative and socially supportive relationships.

Despite this foundation in late nineteenth-century classical sociological thought, research on religion was largely absent from social scientific work in health until the later half of the twentieth century. When such work did appear, it was limited to studies of small, peripheral subpopulations, or to suicide as the only cause of death. Beginning in the 1960s, studies finding lower rates of mortality and morbidity (particularly cancer and hypertension) for clergy, members of religious orders, and certain well-established sectarian groups including Seventh-Day Adventists, Mormons, and Amish, appeared in US medical and public health literature (Jarvis and Northcott, 1987). Work on religiousness and suicide rates also appeared steadily, with generally consistent support for Durkheim's original findings of differences by religious affiliation and also lower rates for those with any religious affiliation (Stack, 2000). All of these studies were based on the comparison of group rates.

An individual-level approach to these questions first came in 1979, when the well-known Alameda County (California, USA) analysis of social networks and all-cause mortality appeared (Berkman and Syme, 1979). It was quickly followed by similar findings from large population studies in Tecumseh County, Michigan (USA), and Evans County, Georgia (USA). In each of these prospective, longitudinal studies, social ties – including ties to religious congregations – were associated with lower overall mortality risks.

These studies were important for many reasons. Until this time, the social environment, long a member of the agent–host–environment triad in multifactorial models of disease causation, had primarily been thought of as having negative influence on health. Social environments were considered sources of stress; social conditions were frequently operationalized as poverty, urban crowding, time-pressured working conditions, or the stress of modern life. The social network studies opened for consideration the possibility that the social environment also provided positive or protective factors in health. The first social network studies were also important because they included multiple types of social ties, including some measure of affiliation with a religious group or attendance at religious services.

Since the 1980s, studies primarily from the United States, but also from Israel, Denmark, and Taiwan, focused specifically on religion as a mortality risk factor; most showed a substantial and significant protective effect of religious participation, even after adjustments for possible selection factors, confounders, and mediators (Idler, 2011). For example, Hummer et al. (1999) found, in a US nationally representative sample, that frequent attendance at religious services reduced mortality risk such that 7 years was added to life expectancy at age 20. These findings were different from the earlier group-level studies of homogeneous religious groups or clergy, in that they represented general populations, with their natural heterogeneity in both types and levels of religious behaviors and beliefs. Like the individual-level social network studies that included other types of social ties, they were longitudinal, and thus were able to adjust for the health status of respondents at the start of the study. Data from prospective observational studies with well-designed health status assessment at baseline is critical, particularly when measurement of the religion variable is limited to the indicator of attendance at religious services. The potential selection effects of healthier members of the population attending religious services more frequently, and being at simultaneously lower risk of mortality, are obvious. Additional important selectivity variables included in these analyses include age, sex, socioeconomic status, education, ethnicity, and marital status, as religious participation is generally higher for women, married couples, blacks, older people, and those with higher education and income. This research is comprehensively summarized by Koenig, King, and Carson; based on evidence from three meta-analyses of the research, they estimate a 37% higher probability of survival for religious participants compared with nonparticipants, after selectivity variables are included (2012, p. 478).

However, a chief criticism of the studies in this rapidly growing field is that most contain only one or two indicators of religiousness, an inadequate level of conceptualization and measurement for such a highly complex set of practices, beliefs, and institutions. Most frequently, attendance at religious services has been the only available measure. When some measure of private religious feelings or practices has been included and compared, attendance is usually the measure with the largest protective effects (Chida et al., 2009). Better measurement of the independent variable is clearly necessary before a larger understanding of explanatory mechanisms can be gained. At the present stage of research, however, several mechanisms through which religiousness might affect mortality have been described.

Reduction of Behavioral Risk Factors

The health economist Victor Fuchs observed in the early 1970s that religious teachings regulate and constrain human behaviors in numerous ways that have known health consequences (Fuchs, 1974, pp. 52–55). He noted the enormous differences in infant, child, adolescent, and adult mortality rates in the two adjacent states of Utah and Nevada. Population density, climate, health care, income, and education levels in the two states were rather similar; any advantage went to Nevada. Yet death rates in Nevada for males aged 40–49 were 54% higher, and for females 69% higher than in Utah. When the causes of death were limited to cirrhosis of the liver and cancer of the respiratory system, Fuchs found that the corresponding figures were 111% and 296%. He attributed the dramatic differences to the 'different lifestyles' of the residents of the two states, Utah being primarily inhabited by Mormons who do not drink alcohol or smoke tobacco and 'in general lead stable, quiet lives' with high marriage and fertility rates and low divorce rates. The situation 40 years later is not different; Utah is the state with by far the lowest smoking rate in the United States and with one of the longest life expectancies.

Most religious groups, however, do not have specific, doctrinal beliefs regarding these behavioral health risk factors, and yet rates for cigarette smoking and substance use are significantly lower, and health promotion activities including exercise and the use of preventive medical care are higher among those who attend religious services regularly, even in studies of religiously heterogeneous populations (Koenig et al., 2012). A US national study of high school seniors found that the more frequent attenders, and those who thought religion was important in their lives, had lower rates of smoking, alcohol, and marijuana use, carrying weapons, getting into fights, and driving while drinking. They also had higher rates of positive health practices such as seat belt use, and eating fruits, vegetables, and breakfast (Wallace and Forman, 1998).

Religious involvement among adolescents that lowers many behavioral health risks is especially important because it represents a lowering of lifetime risks for behaviors (like smoking) that are most likely to begin in adolescence. Moreover, an analysis of data from the Alameda County study shows that religious attenders who do smoke are more likely than nonattenders to quit smoking during the course of a follow-up study, and hence further reduce their mortality risk (Strawbridge et al., 1997). Thus one of the mechanisms through which religion influences health consists of the constraints placed on behaviors that are sensation-seeking, self-stimulating, and that increase risk to the self and others. The reduction in lifestyle risk factors results in lowered rates of lifestyle-related causes of death, and in at least one study a temporal pattern of religious practices preceding risk reduction behaviors has been established.

Enhancement of Social Support Networks

A second mechanism by which the effects of religious involvement may operate is through the expansion and maintenance of social support networks. The study of religion and health is in some ways derivative of the study of social networks and health, and indeed the latter studies provided the earliest modern findings, in Alameda County and elsewhere, as noted above. This mechanism represents the parallel strain in the Durkheimian theoretical tradition, that religious institutions provide both regulation for the behavior of members, as well as integration, or feelings of belonging in a social group. Religious congregants report larger social networks of both friends and relatives, and also more social support from them, compared with nonattenders. There are several reasons why religious congregations would serve as centers of effective social support for members of all ages, and especially for the elderly. Congregations offer a mix of strong and weak ties, and can thus offer a broad range of emotional and instrumental supports. Congregations of all major faiths share values and beliefs about the importance of helping others who are less fortunate and also provide organizational structure for mounting such efforts. Religious institutions provide both support and opportunities to support others, and reciprocal or bidirectional social support may be the most beneficial. Finally, as a corollary of this, members of religious groups who have served others in the past, and who have seen others receiving help, have reason to anticipate support in the future in the event of need.

Population studies of religiousness and health outcomes, particularly mortality, have generally included some assessment of these two explanatory mechanisms (e.g., Hummer et al., 1999; Strawbridge et al., 1997). Usual findings have been that (1) religious involvement, particularly public participation in services, is associated both with better health practices and with higher levels of social support, and (2) these known behavioral and psychosocial risk factors explain some proportion (but not all) of the effect of religiousness on later health outcomes. In studies of healthy populations, then, religion (conventionally operationalized as attendance at religious services) appears to be related to a lower risk of mortality after adjustment for known confounders and selectivity variables, and the effect is partly explained by existing explanatory mechanisms and partly independent of them. This is still an emerging field, however (Ellison and Hummer, 2010). The number of prospective, longitudinal, population-based studies is relatively few, the measurement of the religion variable is unsophisticated, the research has been largely done in the United States in regional samples with Judeo-Christian beliefs, and other explanatory mechanisms should be tested.

Illness and the Search for Meaning

The first part of this article has been concerned with the unintended health consequences of religious practices, or measurable changes in health that result from religious practices undertaken for religious – not health-related – purposes. Equally important for a social scientific study of religion and health, however, are religious beliefs and practices that are engaged in as an individual and social response to illness. Religious groups may offer not only spiritual and tangible support to the sick, including prayers and comforting rituals, but also practical help such as meals, visitation, childcare, and financial support.

Research on the effects of religious coping has frequently taken indicators of mental health and well-being as outcomes. There is a voluminous literature on the types of religious coping, both positive and negative, undertaken by persons with physical illnesses (especially cancer, cardiovascular, HIV/AIDS, autoimmune disorders) and mental illnesses (especially depression, anxiety, substance abuse, schizophrenia) (Koenig et al., 2012). Importantly, not all forms or styles of religious coping may be benign, for example, when the cause of an illness is attributed to moral failure; research is just beginning on maladaptive religious coping and religious struggle (Pargament, 1997).

Classical sociological theories of religion again anticipate these functions of religion in health. Weber's concepts of *verstehen* (understanding the meaning of an action from another's point of view) and theodicy (religious explanations for suffering in the world) provide historical models for the articulation of the problems of individuals with religious language. Religious individuals can draw on the experiences of fellow believers or the stories of their faith tradition to put their own lives into a larger context, to learn lessons from others who have faced similar circumstances, to reduce fear, or to gain hope for the future. Religious ritual practices for mourning or for healing can assist individuals in making transitions to new life stages in which adaptation to loss is required. Religious language and interpretations appear prominently in the narratives of individuals faced with their own aging, or serious illness, or the illness or death of a loved one, situations over which the individual has little direct control, and which may lack clear explanations or challenge beliefs that the world is just (Pargament, 1997). In contrast with the population studies described above, in which attendance at worship services was most predictive of later health outcomes, studies of religious coping frequently find that subjective religious beliefs or nonorganizational forms of religious practice (e.g., private prayer) play an important role.

Religious beliefs and practices are especially prominent in the care for and concerns of individuals at the end of life (Kellehear, 2007). The modern hospice, begun in England in the 1960s, was modeled after medieval Christian institutions that cared for the dying, and the spiritual concerns of patients are still a central aspect of the specialty of palliative medicine. There is also some evidence that the observance of religious holidays may alter the timing of death for elderly individuals; multiple studies in both Jewish and Christian populations have observed short delays before death that permit the celebration of a last sacred ritual (Idler and Kasl, 1992).

Despite a background in the Durkheimian and Weberian traditions of the sociology of religion, the field of research in religion and health remained mostly unexplored through the century, but began growing quite rapidly in the 1990s, especially in the United States, where levels of interest in religion

are generally higher than in Europe. One may anticipate further growth in this field, as the measurement and conceptualization of the relevant domains of religiousness and spirituality improve, and as the population ages and the prevalence of chronic illness increases.

Abstract

Understanding how new media (virtual worlds, the Internet, blogs, social networking, and mobile phones) are being used by religious groups, organizations, and individuals can highlight how social and behavioral changes are manifesting within the twenty-first century. It can be suggested that the prolific uptake of new media has had a direct impact on religious identities, communities, and practice both online and offline. For many, the use of new media enables them to engage with religion on a daily basis. However, it is also being argued that religious use of new media can impact upon users' traditional religion, attitudes, and behaviors.

Introduction

The increasing uptake and integration of new media (such as blogs, social networking, and mobile phones) in the Western society has impacted many facets of contemporary culture including the practices of various religious groups, organizations, and individuals. Most notably this impact can be seen in how religious rituals, identities, and communities are performed and practiced, both online and offline. We argue that by exploring the practices of religion online we can more clearly understand how religion is manifested and conceived of in the wider society.

Over the last 20 years scholars have been paying increasing attention to the relationship between new media, religion, and digital culture, considering how various religious traditions have engaged with online mediums including Paganism (Cowan, 2005), Christianity (Cheong et al., 2012), Islam (Bunt, 2009), new religious movements (Baffelli et al., 2011), and Buddhism (Grieve, 2010). Such examinations of religion on the Internet have been undertaken by scholars of various fields such as psychology, sociology, anthropology, media studies, cultural studies, and within other fields such as religious studies. These investigations have raised a number of questions about the nature of religion and religious practice in digital contexts, as well as highlighting areas needing further examination, such as the four key themes of authority, community, identity, and ritual.

What we are concerned with here are current trends and findings within the study of religion and the Internet and, based on this scholarship, claims about how new media use influences, religious organizations, and individuals. For many, the use of new media enables them to more easily integrate religious practice into their daily lives, for example, accessing the *Qu'ran Reader* for the iPhone, reading the Dalai Lama's tweets or participating in a virtual church, such as the Anglican Cathedral in the online world of *Second Life*. It is also argued that the use of new media can have a direct impact on traditional religious practices and behaviors. Therefore, by analyzing who is using the Internet we can consider whether there are and could be changes to religious authority, community, identity, and ritual – both online and offline.

The Use of New Media and Religion

New media are being used by individuals, organizations, and communities in order to engage with religion both online and offline. The expectation or belief that online religion is distinct from offline religion is no longer accepted as the "Internet constitutes the space where individuals and groups live out their social and spiritual lives, and offline boundaries and relations often inform the online sphere" (Campbell and Lovheim, 2011: p. 1083). Exploring how individuals and groups are using new media can provide an insight into the relationship between culture, new media, and religion within everyday life.

The focus here will be on the exploration of the themes of authority, community, identity, and ritual in relation to specific religions. A number of questions will be considered, such as what are the implications of transporting the spiritual into technological practices; how is religion online reflected in larger societal trends toward lived religion and; how are sources/authorities informing online–offline religious practices in relation to Christianity, Islam, Hinduism, and Buddhism.

Authority

Recent studies have given much attention to the subject of authority and authoritativeness. Scholars have explored how sources and authorities inform online–offline religious practices, as well as highlighting whether we should be concerned that new media could potentially effect religious policy and theology and therefore, challenge authority and authoritativeness (Bunt, 2009; Cheong et al., 2012; Campbell, 2010). Examples of this include Israeli Haredi Jewish communities who have implemented filters and degrees of control on the Internet usage so that it does not violate the moral boundaries of their tradition. Further examples of how religious communities are negotiating the Internet can be found in the Muslim online communities and spaces such as the virtual Great Mosque of Mecca (Ka'ba Shrine) in *OnIslam* in *Second Life* (slurl.com/secondlife/OnIslam/10/54/21). Here, offline cultural behaviors and attitudes are transferred online. For instance, in 2007 when the virtual Mosque came under attack, *OnIslam* responded by putting a sign at the gates of the virtual hajj (pilgrimage site) detailing rules of acceptable behavior in

this virtual space, including no drinking, abusive language, or immodest dress by visiting avatars. In addition, there has been much discussion around the issue of online *fatwas*, which are religious interpretations of the scriptures (Bunt, 2009). The issue of who has the authority to translate the Qu'ran is considered offline but how can this be monitored in the online context? Online there are individuals providing *fatwas*, when offline, they would not be considered a source of authority or allowed to do this. Consequently, online *fatwas* can be perceived by some as less authoritative and therefore challenge 'authentic' Islam and authority. In contrast, the Muslim leader, Seik Al-Qaradawi, maintains that the Internet can 'foster religious identity' and so he has used the Internet to maintain his authority and identity both online and offline (Campbell, 2010: p. 35). Moreover, it has been argued that new media, such as blogs and forums can provide an opportunity for individuals to attain a position of power and authority and become influencers of religious hierarchies and power structures. In some instances, use of new media such as blogs can result in bloggers acting as "armchair theologians or cultural critics" (Campbell, 2012: p. 72).

This paradoxical view of how the Internet can be used to strengthen as well as challenge religious authority is explored by other scholars, such as Cheong, when she considers the paradox of how the Internet simultaneously supports and undermines traditional religious leaders (in Campbell, 2013). This is also highlighted by Baffelli et al. in the context of Japanese new religious movements' use of video sharing sites and interactive Web sites and how they are being used to communicate with followers and challenge other religious movements (2011). What is evident from these studies is the impact that new media is having on various individuals and communities, and it highlights that we need to consider who has the "true legitimate voice for a particular religious tradition or community" (Campbell, 2012: p. 76).

Community and Identity

In recent days, scholars have argued that it is important to understand trends within religion online in light of how this reflects larger societal trends toward lived religion, where every day lived religion is often more dynamic and fluid than religiosity prescribed in traditional contexts. This is clearly shown in how individuals create or negotiate religious community and identity online. Networked communities and associated identities developed online are often associated with the character of those rooted in offline community, such as virtual churches drawing their architecture or patterns of life from offline structures. *Second Life* (Anglican Church), blog communities, or on social media sites (e.g., YouTube, Facebook, Twitter). By studying networked religious communities we are able to see how "people in contemporary society live in religious social networks that are emergent, varying in depth, fluid, and highly personalized" (Campbell, 2012: p. 71) as they draw from multiple sources in the creation of online religious communities. Furthermore, the construction of identity may vary and allow for "dynamic opportunities for self-expression" (Campbell, 2012: p. 71). This is clearly evident as individuals may create and maintain multiple online personas on different digital media platforms for different motivations. A prominent example of the establishment of an online persona is the creation of an avatar in a virtual world. The avatar is a flexible identity that may engage in religious or secular activity and can change their appearance to reflect different identities, such as the wearing monastic robes or animal likenesses, thus demonstrating the ability of users to freely explore and construct unique religious identity presentations online. Another example of new media assisting self-expression is blogging. Blogs provide a platform in which religious imagery or language can be used to present and represent the belief structure of the author or enable them to self-reflect on different expressions of spirituality within the wider participatory culture of the blogosphere. Understanding the nuances and complexities of religion online and how new media can assist with creating and developing religious communities and identity can provide a clearer description of religion today.

If we look at this more closely in relation to Christianity it is possible to highlight examples of these trends within online religious communities and identities. Initially it was perceived that the use of the Internet by Christians might become a substitute for offline religious engagement, however, research has shown religious users involved in the formation of communities and online Christian identity to do this to supplement offline religious involvements. For example, blogging has become away for individuals to connect with like-minded communities where they can construct a shared religious identity via stories and behaviors. Also Christian communities have actively embraced new media to spread the Word and engage with other Christians from around the world, linking the online and offline context through integrated patterns of ministry and worship.

This is illustrated within the Anglican Cathedral in *Second Life*, a community of 500 members attending multiple weekly services in a virtual cathedral on Epiphany Island (Campbell, 2010: p. 126). The cathedral "was birthed through the vision of a small group of Episcopalians and Anglicans from the United Kingdom, New Zealand, and the United States, who met informally in Second Life" and who are potentially "reconfiguring religious practice online" (Campbell, 2010: p. 123). This online community holds services, which draw from both "traditional and contemporary styles of worship," in addition to taking into account the different time zones from around the world as well as designing the cathedral to replicate an offline cathedral, possibly to further legitimate the authenticity (2010: p. 123). One of the areas for concern is that "the online cathedral challenges traditional notions of authority and accountability" (2010: p. 124). These challenges are further highlighted, when in 2008, Mark Brown became a licensed minister for this virtual community, possibly providing the online community with "offline legitimacy" (Campbell, 2010: p. 126). The use of *Second Life* to expand the Anglican community is not without its challenges, although there are also opportunities, such as the potential for creating a virtual theology and establishing virtual Christian communities with a wide outreach, to members of the congregation across the world.

Ritual

When considering the implication of transporting the spiritual into technological spaces, a number of considerations arise,

such as the extent to which religious practice can be adapted to the Internet; the authenticity of a blended form of religion online; and how adaptations of religious behaviors may coalesce or undermine given belief systems. New media provide a way in which individuals can engage with and practice religion and in some instances transform ritual. However, unlike some aspects of traditional religion, new media enables the user easy access to the religion and to personalize it to their own needs. This personalization can result in what is seen as a 'pick and mix' or individualistic style of religion, and consequently, behaviors and belief systems can become merged, altered, or completely changed.

New media ritual can come in many guises including, Buddhist meditation, Hindu puja (worship), pilgrimage (e.g., in OnIslam in *Second* Life), and prayer facilitated via smartphone apps. The study of ritual online has been undertaken by Helland (2007), who argues that ritual can be both a religious and a secular act and therefore rituals are meaning-making systems. His examination of early USENET groups aimed to determine why such groups form and what they can provide for many individuals who are "geographically dispersed" (2007). Early Web sites were limited to textual interaction or broadcasting live events (e.g., online events, festivals, or worship). However, with the introduction of new media, there is the potential for visual, audio, and virtual selves engaging with others from around the world and actively participating in religious rituals.

Helland also examines Hindu rituals such as puja online and argues that although participants "are not there in person, their Web presence is felt, and they are conducting an authentic religious activity and receiving the benefits of that activity" (2007). He also considers three questions: Is the Hindu ritual, traditionally found in the home, moving to the home computer? Is the person "undertak[ing] an authentic and significant religious activity?" and Is online ritual assisting the wider diaspora? (2007). Answers to such questions may vary from religion to religion but for many, the ritual via new media is authentic and part of their everyday lives. This is further illustrated by Wagner who explores the use of smartphone mobile apps and how they can provide a means of engaging with religious ritual whenever the user wishes. She argues "that we can learn something about our streaming selves by looking at how we use, display, and interact with religion via our mobile devices" (2012: p. 105).

The authenticity of online ritual as well as the negotiation between offline–online spaces is acutely seen in *Second Life*. An avatar can prostrate on entering the virtual Buddhist temple, present an offering (donation) of Linden dollars (*Second Life* currency), and spin a virtual prayer wheel, thus suggesting an authentic experience by imitating offline practices. This raises questions as to whether or not a Buddhist virtual ritual can result in the same meritorious acts found offline. For some of the creators of Buddhist virtual objects and places, they argue that as long as the ritual is done with the same intention found offline, then it can result in merit for the online participant (Connelly in Campbell, 2013). It is clear that how people engage with and practice religion can change the dynamics of traditional religion (Campbell, 2012: pp. 76–77), but it can also provide us with an insight into how religious cultures are changing and how individuals are using new media for religious rituals.

The Emergence of the Study of Religion and the Internet

The academic study of religion and the Internet can be traced back to the mid-1990s when early works documented the emergence of religion online and specific practices such as Stephen O'Leary's (1996) observance of the Internet rituals enabling the re-imagination of religious sensibilities online. These early works explored a number of significant questions, such as 'Who is using the Internet?,' 'What are they using it for?,' and 'How are they using it to access religion or religious information?' Scholars, such as Dawson, noted the majority of research in the early stages focused on "identification and measurement" (Dawson in Cowan and Hadden, 2000: p. 26) and found a number of common research areas including the study of 'the nature and quality of people's experiences' in terms of religion, attempts to understand the negotiation of religious practice offline and online; identifying the implications of technology on religion; and considering whether one type of religion is more suited to the Internet than others (2004: pp. 10–11).

These research areas were explored in detail in three important edited collections. *Religion on the Internet: Research Prospects and Promises* (Cowan and Hadden, 2000) offered a comparative approach gathering key case studies within the initial wave of Internet scholarship, offering primarily descriptive research often contextualized within a utopian or dystopian Internet paradigm. Other important descriptive studies include Cowan's comprehensive account of paganism online in *Cyberhenge: Modern Pagans on the Internet* (Cowan, 2005), where he illustrates how Pagans use the Internet for the formation of cybercovens and the impact of online forums and informational Web sites on pagan practices. This documentary work highlights important research themes of the nature of identity, community, and authority online. Cowan explains that online pagans challenge previous notions of who or what is considered authoritative or authentic within pagan traditions. Thus initial, or what is called first wave research, sought to define and document the rise of different features of religion online.

The second collection is *Religion Online: Finding Faith on the Internet* (Dawson and Cowan, 2004), which marked a move toward more detailed analysis and refined methodological approaches. Questions were raised about particulars of studying religion online, such as what were the common forms of religious Internet practice and unique relationship between religion online and offline. Within this second wave there was a move toward categorization as an important study such as Helland's typology of religious Web sites as either 'religion-online' (informational) or 'online-religion' (participatory) (2000). There is a general consensus that there is no longer such a clear demarcation between the two. Yet it served an important purpose providing scholars with critical categories for evaluation of religious presentations online.

In the third collection *Religion and Cyberspace* (Hojsgaard and Warburg, 2005), the concept of three waves of research was introduced and later refined as "the descriptive, the categorical, and the theoretical" trends in scholarship (Campbell, 2013). Hojsgaard and Warburg used the metaphor of the third wave to highlight the theoretical and methodological turn

in scholarship of religion on the Internet. Here scholars have tried to consider what studies of religion and the Internet demonstrate about the nature of social relations and the practices of religious communities within wider cultural spheres. We also see movement toward providing theoretical interpretive frameworks, such as the religious social-shaping of technology (Campbell, 2010) to explain religious decision-making regarding online and technology practices.

The study of religion online continues to be given attention by different fields of scholarship and organizations such as the Pew Internet and American Life Project (http://www.pewinternet.org/). They published two key reports on this area including *Cyberfaith: How Americans Pursue Religion Online* report (Larsen, 2001) and *Faith Online*, which found that 64% of Americans have used the Internet for religious purposes (Hoover et al., 2005). This growing interest has also resulted in a number of dedicated journals or special issues such as *Religion* (2002), *Journal of Computer-Mediated Communication* (2007), and *Information, Communication and Society* (2011). In 2005, the Heidelberg *Journal of Religions on the Internet* (http://online.uni-hd.de/) was founded to consider issues of methodology, aesthetics online, and religious rituals on the Internet. For example, in 2010, the special issue focused on aesthetics online and articles in this issue examined the online Jewish prayer wall, Buddhist temples in *Second Life*, online churches, bloggers, and Hindu worship (*puja*). This dedicated focus shows that the study of religion and new media is increasingly recognized as a valid and vibrant subfield of Internet studies within the new field of media, religion, and culture studies.

Current Approaches to the Study of Religion on the Internet

This section presents the current approaches to the study of religion, highlighting the key questions while referring to the four themes: authority, community, identity, and ritual. A number of questions are raised and areas considered include, how new media are being embedded in everyday (religious) life; the concerns or challenges arising from using new media; and the unpacking of the online/offline context (Campbell and Lovheim, 2011; Wagner, 2012). Campbell and Lovheim claim that "after a decade and a half of published research on religion online, we are finally able to begin to make some educated claims about the impact of the Internet on religious culture and social forms" (2011: p. 1). The early waves of research primarily focused on descriptive accounts but recent research has begun to include more refined methodologies and typologies for interpreting and categorizing religion online, and offline – which some claim is the emergence of the fourth wave of research (Campbell and Lovheim, 2011).

Current approaches to the study of religion and new media include more comparative work across different traditions and cultural contexts, and a push toward more nuanced cultural considerations of dynamics and the relationship of religion online and offline. One area that has been given much attention is the online/offline demarcation of religious behavior and practice (Dawson and Cowan, 2004; Helland, 2000; Campbell and Lovheim, 2011; Campbell, 2012, 2013). There is now consensus that there is no longer a clear demarcation between offline and online and that new media are enabling an integration of the offline and online religious contexts, while potentially challenging traditional models of religion.

Furthermore, in *When Religion Meets New Media*, Campbell argues that there are two trends emerging, namely the growth in "new media alternatives" and the response from "conservative communities" and their use of new media (Campbell, 2010: pp. 191–193). Prominent examples of 'new media alternatives' are 'godcasting' (religious podcasting, www.godtube.com), Christian blogs (www.christianblog.com/), Islamic forums ("ask the Iman," www.islam.tc/ask-imam), and online Hindu worship known as *puja* (Rudra Centre, http://www.rudraksha-ratna.com/). The consideration of 'conservative communities' use of new media includes religious authorities engaging with new media in order to stay relevant; communities and authorities trying to take control of new media in order to 'support their position'; and offline communities evaluating the impact of new media on their tradition (Campbell, 2010: pp. 192–193). Examples of this include the Vatican adoption of a YouTube channel and Japanese new religious movements using video sites to engage with followers; yet at the same time seeking to maintain tight control over how the medium is used, such as restricting or disabling the comments feature (Campbell, 2010: p. 192; Baffelli et al., 2011). This clearly highlights the contention between traditional religion, authority, and the use of new media and that "authority is clearly challenged by emergent digital cultures" (Cheong et al., 2012: p. xi)

The relationship between cyberculture and religion has been considered by Campbell and Lovheim who emphasize that "religion has not only been impacted by, but also impacts" (2011: p. 1084) and they consider whether technology shapes religion or if religion shapes technology (2011: p. 1088). The themes of authority, community (or belonging), and religious practice can be explored and answers sought to how individuals, communities, and groups are "negotiating between the requirements of establishing a successful online presence and traditional criteria for legitimate knowledge, expertise or sincere commitment, often based in the conditions of offline contexts and sources" (Campbell and Lovheim, 2011: p. 1089). Moreover, studies of how new media are being used and the impact they are having and how religious culture may change are being given considerable attention (Campbell, 2013; Wagner, 2012).

This impact as well as religious and technological influence can be illustrated by looking at the user of mobile and smartphones. With the significant increase in the user of smartphones, we can consider the use of the religious app. In the context of identity, Wagner examines the use of smartphone apps to engage with religion and create religious identities. She presents six types of apps, which are (1) prayer apps, (2) ritual apps, (3) sacred text apps, (4) social media apps, (5) self-expression apps, and (6) focusing/meditation apps (2012: pp. 102–105). She argues that the religious app enables a more individualistic style of religion and the collection of apps on the smartphone relates to our own unique religious identity. Furthermore, she maintains that the ritual via the app is not facilitated by 'recognized religious authorities' but by anyone who owns a smartphone (2012: p. 105). This form of new media differentiates itself from other forms,

where the intention is to build online communities or be an extension of an offline community. Instead, the mobile app provides access to religious prayers, scriptures, rituals, and information as and when the user wants to engage with their religious practice.

Future Areas of Research

As new media emerges, changes, and grows in popularity, there is scope for further research and the refinement of existing approaches to the study of religion and new media. There are a number of areas, which need to be considered within the wider social and behavioral context and some of which align with Dawson's initial research concerns (2004: pp. 10–11). This would include, but is not limited to, the impact of those who have Internet access and those who do not and whether there is a growing digital divide between different religions or individuals use of new media to engage with religion; how new media are being used to assist with marketing and selling of religion, for example, the use of social networking sites to advertise nontraditional as well as traditional forms of religion; unauthorized surveillance of religious groups or restricting access to certain Internet sites (e.g., in China) (Campbell and Lovheim, 2011: p. 1093); the impact of changing technology on religion – good and bad – for example, the rise of the mobile apps to engage with religion 24/7 and which could be perceived as a more personal form of religion (Wagner, 2012); and understanding the manifestation of religious experience within the online context, such as engaging in virtual ritual in *Second Life* and this resulting in an authentic religious experience for the participant.

Another area which has been specifically highlighted for further investigation is Asian religions on the Internet, especially Buddhism (Campbell, 2010: pp. 190–191). Some work is emerging in this area and focusing on Buddhism in the online world of *Second Life* (see Grieve, 2010; Connelly in Campbell, 2013) and new religious movements (Baffelli et al., 2011). There are two other significant emerging areas, including the proposal of a subfield, 'digital religion' (Campbell, 2013) and the theoretical concept 'networked religion' (Campbell, 2012). In *Digital Religion: Understanding Religious Practice in New Media Worlds* (2013), Campbell argues that the subfield of 'digital religion' can be defined as the social and technological space, which is evoked or created when we consider how online and offline religious spheres merge and interconnect within digital culture. Thus digital religion can be used as a term to describe to the connection and extension of online religious practice and spaces into offline religious contexts (2013). An example of digital religion can be found in *Second Life*, where there is the simultaneous practice of Buddhist meditation offline and online. This manifests via the instruction of a Zen Buddhist priest online, however, there is the expectation that the avatar in *Second Life* is meditating offline, in accordance with the online instruction (Connelly in Campbell, 2013).

In addition to the proposal of the subfield there is also the introduction of the concept of 'networked religion.' This is used to describe how religious practice online parallels with social and religious practices offline, and represents the "social reality of life in a networked society" (Campbell, 2012: p. 66). Significantly, Campbell maintains that the naïve assumption that religion online ultimately and totally transforms religion offline is too simplistic, instead a nuanced exploration of the interrelationship of religion online and offline is required. Networked religion is characterized by five traits: convergent practice, multisite reality, storied identity, networked community, and shifting authority. "Together, these characteristics present an understanding of religion that is informed by a dynamic and integrated relationship between the sacred and the mundane online" (Campbell, 2012: p. 65). Understanding the complexity of the relationships, behaviors, and experiences offline can explain the choice of technologies and behaviors, experiences, and religious communities used online. This highlights how religion online shapes and reflects a nuanced view of religious practice in contemporary society.

The future direction and continued study of religion and new media is also suggested by the establishment of the *Network for New Media, Religion and Digital Culture Studies* in 2011 and its associated Web site launched in 2012 (http://digitalreligion.tamu.edu/) and the *Journal of Religion, Media and Digital Culture (JRMDC)* (*http://jrmdc.com/*) launched in 2012, both which seek to connect interdisciplinary scholars and promote the work of the study of religion and new media. The development of networks, journals, and conferences further emphasizes that the relationship between new media, religion, and culture is of significant interest if we are to understand the implications this may have on wider society and specifically religious authority, community, identity, and ritual.

Conclusion

What has become apparent in recent years is that there are a number of parallels between the offline and online religious culture, behaviors, and practices. This is clearly evident when discussed in relation to the four common themes of authority, community, identity, and ritual. The cultural contextualization for understanding how new media are being used, for what and by who, is similar to the approach for understanding the nuances of online religious culture, individuals, religious groups, and organizations who are embracing or rejecting new media as a medium for religious practice, information sharing, and communication. We have highlighted a number of issues, including the challenge to traditional religion and ideologies; the potential change from a communal to an individualistic form of religion, such as those engaged with via the religious app (Wagner, 2012); and the issue of wider social or political constraints placed on using different technology, for example, access to particular Web sites or social media in countries where some new media are banned (e.g., Facebook in China). What is not clear is whether new technologies and the constantly changing landscape of new media will radically alter religion.

By focusing on the relationship between religion and new media it enables a greater understanding of how to approach the examination of this topic, including the need to adapt existing methodologies or develop new ones; as well as highlighting what areas require further exploration. The study of media, religion, and culture has been framed within the three

and four wave context and in doing so this has helped to pin point key developments in the history of this field. We have also seen that fully understanding the relationship between new media and religion requires interdisciplinary working between a variety of fields and areas of inquiry (see Hojsgaard and Warburg, 2005: p. 9; Campbell and Lovheim, 2011: p. 1093)

The overview provided here illustrates that this topic can be discussed within the theoretical framework of 'networked religion' and positioned within the emerging subfield of 'digital religion.' Future research may address Dawson's research areas (2004: pp. 10–11), including more in-depth comparative approaches and longitudinal studies, in order to gain further insight into whether religion is being impacted by new media. This constantly changing landscape and the increasing introduction of new technologies provide new possibilities and potential challenges to religion, behavior, and culture, how we explore and negotiate these changes needs further consideration.

Religion and Politics in the United States

Abstract

The character of religious engagement in U.S. politics is powerfully shaped by the First Amendment to the Constitution that established a religious free market. Competition encouraged a vibrant, inclusive, comprehensive organizational presence, in which religious organizations face internal disagreement as well as external value threats. Neither is stable, which means religious organizations continually battle a two-front war, and will come in and out of politics. Because of this, we should expect a dynamic, variable presence of religion in American politics.

Although most advanced industrial democracies have a public square denuded of religion, the United States is exceptional. The vast majority of Americans are religious by at least minimal measures, and substantial pluralities are religious in a more robust sense. Religious symbols are expected to be invoked by public officials, and they are. Yet, the connections between religion and politics are diverse, often contradictory, and undermine confidence about speaking uniformly of any particular effect religion has. This article examines these varied connections to understand religion's connection to democracy in America.

Definitions

Religion is a multilevel concept that gains shape through the often-federated organizational structure of recognized religions; the beliefs, values, and practices of individuals and social collectives; and the symbols (or cues) that people use in everyday communication. Religious actors can be average citizens, clergy, organizational elites, and office holders. Politics is individual and collective commitments that bear on government decision making; it is not just the exercise of power in everyday life, but rather it concerns the opinions people have as well as the behaviors people and organizations engage in to affect their interests through government. Politics in the United States often aspires to be democratic in the sense that it supports the maintenance of a limited state, but it also functions under a set of rules establishing the equality of participants and a near-universal ability of citizens to participate.

Democratic Roles for Religion

If the central democratic problem is how to resolve difference peaceably and not fall prey to the violence of faction, then scholars have rightly devoted their time to resolving it. The primary author of the U.S. Constitution and future president James Madison advocated a pluralist solution in Federalist 10 – the 85 *Federalist Papers* were written for New York newspapers from 1787 to 1789 to encourage states to ratify the drafted Constitution. Madison's solution was to embrace difference and rely on the checks and balances that competing interests will place on each other to achieve stability. In essence, diverse nations will aggregate diverse representatives who will not suffer proposals that cut against their interests. Religious diversity is important in this scheme because many see their aims as nonnegotiable, thus their vigilance will remain high to identify efforts that deviate from intractable religious scripts.

Tocqueville documented a considerably different phenomenon. Instead of a nation cleaved by difference, Tocqueville observed a nation united in good citizenship – personal responsibility was prized and local associations of all kinds, religious and not, were formed to resolve collective action problems. Importantly, religion undergirded this system, which enabled government to innovate on the security that the citizenry was essentially self-sufficient and without the strife that overt religious participation in politics had brought to European nations. If a pluralistic religious society meant stability through disagreement and discord to Madison, for Tocqueville, it meant precisely the opposite.

These two solutions also found their locus in vastly different mechanisms. Madison's approach vested institutions with the power to resolve democracy's contradictions; Tocqueville, on the other hand, clearly saw the solution rooted in value systems and social control outside of politics (see also Durkheim, 1965/1915). These divergent perspectives eventually coalesced into a deliberative theory of democracy (Gutmann and Thompson, 1996), which provides institutional elements that consciously aggregate different views among people committed to working together for a common solution. It is easy to imagine representatives of different religious groups sitting at the negotiating table, but there are features of the U.S. system that promote exposure to and engagement with difference within religious organizations as well. Although there are other approaches to the relationship between religion and democracy, including militant separation and a gentler sense of religion as a refuge (Fowler, 1989), these three perspectives (Madison's pluralism, Tocqueville's communitarianism, and deliberative democracy) encapsulate the style and content of the political *engagement* of religious interests.

It is remarkable that, by at least one measure, the United States has been a Christian nation only relatively recently. Church adherence was quite low at the founding (about 17%) and steadily increased to a plateau for the past 40 years around

62% (Finke and Stark, 2005: 23). With the ratification of the Bill of Rights in 1789, the U.S. Constitution established structural boundaries for the religious marketplace in America, at least on the federal level. With the First Amendment's religion clauses, the Constitution prevented the U.S. Congress from making laws 'respecting an establishment of religion' or 'prohibiting the free exercise thereof.' These two requirements, in addition to the prohibition of religious tests in Article VI of the Constitution, created a federal order much different than the European models and established a religious free market. Christian religions flourished in many forms in this unregulated space (and other religions did later). To effectively compete, religious entrepreneurs appealed to a particular community's needs and developed comprehensive and diverse sets of social, spiritual, and service programs to help meet them. Even if successful religious groups maintained high boundaries with the world, the drive to grow congregations dictated an essentially inclusivist orientation. Together, this placed religion as central organizations in people's lives, imbued many aspects of life for adherents with religious symbols, and gave adherents organizational experience, all of which have political consequences.

Constitutional Bounds

The market is not entirely free and the particular boundaries of it have shifted over time. Because of the federalist relationship between the national and the state governments, the constitutional structure protected state establishments of religion and state oaths of office that included religious items, some of which lasted into the nineteenth century (Curry, 1987; Dreisbach, 1996). Since the Constitution's religion clauses limited their application to the federal government, the U.S. Supreme Court did not adjudicate religious matters until the twentieth century, with a few exceptions. Per the constitutional order, there was no threat of a national church, although a generalized version of Protestant Christianity dominated American culture and politics for the first 150 years (Hamburger, 2002). By the mid-twentieth century (see *Cantwell v. Connecticut*, 1940; *Everson v. Board of Ed.*, 1947), the Court had applied its incorporation doctrine to the religion clauses. This applied the religion clauses to the states and initiated more than 70 years of intense debate regarding the prudential role of religion in public life.

The debate centers on competing views of religion's role in society that roughly parallel the tension between Madison's and Tocqueville's views. In free exercise case law, the Court must decide whether to permit practices that stray outside the mainstream, including anti-Catholic speech (*Cantwell*, 1940), keeping children from public schools (*Yoder*, 1972), peyote ingestion (*Smith*, 1990), and animal sacrifice (*Lukumi Babalu*, 1993). In establishment cases, the Court considers the opposite – state support for the majority. The dividing line lies at the intersection of pluralism, in which diverse perspectives keep society in check, and communitarian impulses that generate concern for maintaining a core to American culture.

In the modern period, free exercise decisions were weighted in favor of pluralism through the use of the 'compelling state interest' test, which places a heavy burden on state action that restricts religious practice. State support for religion was not given the same scrutiny. The Court promoted a strong antiestablishment perspective and initiated a 'wall between church and state...[that] must be kept high and impregnable' (see *Everson*, 1947; see also *McCollum*, 1948). At times, the wall did not look impermeable. The Court frequently allowed indirect aid to religion (e.g., *Everson*, 1947; *Walz*, 1970), while typically opposing direct aid or preference for religion (e.g., *Engle v. Vitale*, 1962; *Nyquist*, 1973). The wall that separated church and state reached its apex with *Lemon v. Kurtzman* (1971).

In the past 25 years, there have been revisions to both doctrines, effectively weakening both the free exercise and the establishment clauses. In *Oregon v. Smith* (1990), the Court dramatically changed the direction of free exercise law by refusing to carve out exceptions to a neutral law, with the exception of the right to hire and fire on the basis of religious belief (*Tabor v. EEOC*, 2012).

Free exercise rights were limited by a single case, but the limiting of the separation of church and state was a slower process as the Court steadily built precedent sufficient to allow state support for everyday religious organizations involved with secular programing, especially education. The shift sidestepped the establishment clause, arguing that the freedoms of speech and association prevent government institutions from discriminating against religious groups. Doing so has gained religious entities equal access to public facilities and public funds for students to attend private religious schools, among other things, that led one prominent legal scholar to declare that 'the constitutional era where separation is the dominant theme appears to be over' (Lupu, 1991, p. 557).

Religious Institutions and Politics

If Tocqueville was ever right that organized religion was content to remain outside of politics (see Hatch, 1989), the observation did not stand for long. Religious interests have been primary advocates in not just constitutional battles, but in a very broad set of political debates from issues as mundane as zoning, to self-interested concern for public support for social services, to cultural issues like same-sex marriage (see Djupe and Olson, 2007). Baptists and other religious minorities encouraged federal and state governments to formally disestablish religion in the founding period (McLoughlin, 1971). Jehovah's Witnesses and Mormons brought some of the early suits to extend free exercise rights, and most major religious organizations continue to work together to promote broad religious freedoms. Jewish organizations, along with Baptist and Mainline Protestant denominations, have been active in promoting the separation of church and state, whereas Catholics and evangelicals have championed the non-preferential and accommodationist interpretations of the establishment clause (Teles, 2007; Jelen, 2000).

The interests of religious organizations are much more extensive than the First Amendment and precisely because of it. That is, houses of worship and denominations developed comprehensive social service programs, which naturally invested them in governmental development of the welfare state. In the twenty-first century, very many groups maintain permanent representation before government, though often tempering

their advocacy because of internal disagreement among members of faith groups (Hertzke, 1988; Hofrenning, 1995). Moreover, members often know little about the work of denominational lobbies, even as they are careful to populate their agenda with broadly supported issues.

Clergy might also be thought to play a representational role, although there is considerable variance in whether they represent the faith or the faithful. When their congregations are underrepresented in the community, they tend to take a more active political role encouraging political engagement (Djupe and Gilbert, 2003). There is still debate about whether congregational clergy act in prophetic ways to challenge their memberships or whether they hew their agenda closely to safe positions. Clergy typically are able to find reference groups supportive of their positions (Calfano, 2009), while they are also sensitive to maintain member support, which is largely driven by a satisfactory experience with congregational programing. Studies that attempt to unravel the interplay of these reference systems are particularly needed.

Given that congregations face competitive pressures, they cast a wide net for new members and often aggregate a wide range of people (Wald et al., 1988). Thus, across denominations, clergy are by default inclusive and respectful of individual differences (to varying degrees, of course). Clergy typically face a significant degree of diversity in their congregations and often employ democratic norms (equality, mutual respect, and full participation) to govern congregational groups, even if they do not share that commitment privately or in their public speech. While many clergy, value democracy in its own right, it is easy to find examples of clergy promoting intolerance of a wide range of groups. The conditions under which clergy become 'republican schoolmasters' (Franklin and Liane, 1989) are deserving of further study.

Religion and Political Movements

In certain periods, religion has helped spark political movements in America, not merely political advocacy. These movements are defined by 'the mobilization of previously unorganized or non-political challengers' (McAdam, 1999: xxv), whereas ordinary political advocacy occurs through established lobbying organizations and networks. In the history of American democracy, religion has played an important role in many social and political movements. In the modern era, nowhere has this been more evident than the civil rights and the Christian Right movements.

To be successful, movements often appropriate existing organizational structures, and religious organizations, as the most widespread social organizations in America provide effective grassroots networks (Wald and Calhoun-Brown, 2011). Churches and churchgoers are not, by their nature, typically engaged in political advocacy. At certain times, however, some have become central to political movements. The civil rights movement was rooted predominantly in local African-American churches, which previously has been a conservative force in the black community and opposed to political activity (Morris, 1984). Evangelicals, the prominent religious group in the Christian Right, were also initially reluctant to engage in politics. Their beliefs about a supposed cultural and moral decline, including expanded abortion rights, acceptance of nontraditional sexual practices, and the decreased role for public religion spawned mobilization. These culture war issues brought together committed, orthodox faith communities (Hunter, 1991) – spurred by prominent pastors, entrepreneurial laypeople, local church networks, and grassroots organizations (Green, 1997) – and made a central connection to the Republican Party. Cultural politics can provide an important opportunity for the minority party, and Republicans utilized the discontent among religious conservatives to their advantage (Leege et al., 2002).

Religious political movements have had an important impact on American public policy and the political landscape. Religious activists in the civil rights movement achieved legal, political, and cultural change. The Christian Right movement has kept their issues on the political agenda, although there was limited success in changing state or national policy (Green et al., 2003) until recently. The Christian Right arguably has been most effective in securing a 'seat at the table' for conservative Christians (Wilcox and Larson, 2006), especially within the Republican Party, expanding the rights of the religious and mobilizing in support of ballot initiatives.

Like all social movements, religious political movements face difficulties in formation and maintenance. The civil rights movement waned when windows of opportunities closed, organizations fractured, and resources decreased (McAdam, 1999). The Christian Right has been plagued by internal conflict, lack of cooperation between groups, difficulty in mobilization, an intense countermobilization by opponents (Green, 1997), and steady integration into regular, Republican politics. The movement's diversity and complexity have inhibited scholarly assessments of Christian Right mobilization. Some suggest that psychological attachment and collective identity drive mobilization (Wilcox et al., 1993). Others have argued that Christian Right mobilization transcends denominational identities and conforms to a broader culture wars perspective (Wuthnow, 1988).

Because the key factor of a movement is organizing the previously unorganized, movement participation provides political skills and experiences, expands social networks, and engages people with political organizations. In this way, both the civil rights movement and the Christian Right movement have expanded the bounds of our representative democracy (but see Claassen and Povtak, 2010). At the same time, religious movements have a tendency to inflame conflict. Cultural politics, a key focus of the Christian Right, may be detrimental to democracy by promoting polarization (Layman, 2001) and restricting compromise and other democratic norms (Wilcox and Larson, 2006). This culture clash is largely absent from the mass public (Fiorina et al., 2006), but its presence in elite and niche politics may counteract some of the benefits of enhanced political participation that religious movements provide. Continued research comparing the positive and negative influences of religion on democratic participation is important.

Religion and Political Behavior

While religion has been tied to political movements, it is necessary to understand how this relationship occurs. Religious

influences on citizen political behavior are varied, and sociological and psychological theories contend to explain the connections between religion and political behavior. Religion often provides local organization in which people learn about the political choices of fellow citizens and of religious leaders (Djupe and Gilbert, 2009). Religion is a set of beliefs and values that individuals can use to cognitively structure their political choices (Barker and Carman, 2000). Religion also can be an identity that allows individuals to parse the world into ingroups and outgroups (Jelen, 1993), which helps establish trust in an information source. Religion also can be a set of cues that elites use to communicate ingroup solidarity and political content to potential followers (Leege et al., 2002). There is no reason to assume that these religious mechanisms combine to produce consistent attitudes and behaviors, but examining the conditions when they do is an important question.

The study of religious influence on environmental attitudes offers an ideal vantage point to observe these three perspectives at work. The earliest work by Lynn White argues that Christians believe that humans have dominion over the Earth and therefore are more indifferent to environmental protection. Subsequent research has refined and qualified this finding, with substantial disagreement depending on the measures used. Opposition to environmentalism has been limited largely to conservative Protestants, a finding that supports many interpretations, including the identity-based treatment that environmentalists are not Christians and environmental initiatives place nature over humans (which earned environmentalism the label satanic from the late Rev. Falwell and others). Strikingly, religiosity has been found to have positive effects on environmentalism especially when the specific belief that believers are stewards of the Earth is examined (Sherkat and Ellison, 2007). In the late 1990s, opposition to environmental measures was correlated with biblical literalism, as a proxy for a belief in human dominion over nature and as a belief in the immanence of the end times (Guth et al., 1995), but the effect faded to insignificance once more salient and particular beliefs were considered.

Environmental attitudes have changed considerably over the past 40 years in all sectors of society, including among religious traditions at the same rate. Since religious beliefs and practices have not changed much within religious traditions, something else must explain the shifts. Complicating the relationship, we know that religious beliefs relevant to shaping environmental attitudes come from a house of worship, which also conveys political opinion content through sermons and other sources directly to members. This raises the specter that religious belief effects are, in fact, spurious and dissipate once actual political communication on the environment is measured. Moreover, evangelicals are willing to become more environmentally friendly when cued by an identifiable ingroup elite (such as Rev. Rich Cizik, formerly of the National Association of Evangelicals). Taken together, religion exerts a variety of forces on opinion and also shows that connections between beliefs and opinions can be reinterpreted in the face of social (and elite) pressures. Few other opinions have been as thoroughly investigated as environmental support, but we suspect that similar, fundamental disagreements between theoretical perspectives would arise elsewhere.

There is less disagreement in the literature on religion and political activism. Most would agree in broad brush with Leege that "People (who) share a sacred community … develop the self-confidence to act in concert. Religion specifies what action to take, and religious beliefs (and religious institutions) create the obligation to act" (Leege and Kellstedt, 1993: 10). However, the precise mechanisms for each component and the degree to which participation is coordinated and aggregated by the congregation are less well known. And, curiously, little to no work has investigated religious coordination of the content of political activity.

Research acknowledges the importance of the organizational church, which offers opportunities to develop motivation, practice politically relevant skills, and be asked to take part. Studies locate organizational influences not in worship attendance but small group participation (Leege, 1988), where individuals meet face to face and enjoy leadership opportunities. Other literature, particularly in studies of the black church, places particular emphasis on religiosity as a mechanism that develops efficacy (Calhoun-Brown, 1996). Progress in this area will come from understanding why particular congregations develop a participatory infrastructure and asking whether resources from particular congregations translate to political activity at different rates. One promising avenue is to explore the link between participation and political communication in the congregation – initial work finds that civic skills practiced in nonpolitical churches have no relationship with political participation (Djupe and Gilbert, 2009: Chapter 5). Others should explore the long-asserted, little-tested links between congregations and interest groups, and community and congregation, especially if congregations help magnify parties' efforts to get out the vote.

Conclusion

Leege concluded the previous article in this volume with "Basic problems of conceptualization and measurement, underspecified models, endogeneity, failure to anchor puzzles in strong social theory, and inappropriate samples continue." Many of these problems persist after a decade but much abated. If religious influence is composed of the full range of social and psychological mechanisms and a multitude of actors, then existing studies of religion and political behavior are still highly fragmented, typically examining just one at a time. The unifocal character of most studies limits the development of covering theories and weakens our understandings of the sum and consistencies of religious influence. Two paths forward are recommended. One promising opportunity is greater use of experiments that allow for the controlled introduction of information from an actor in novel settings to help resolve the ambiguity of causal claims (see Djupe and Calfano, 2013). Equally promising are studies that combine data from across levels of analysis, such as congregations within denominations, clergy and congregations (Djupe and Gilbert, 2009), members and clergy within denominations (Lewis, 2011), clergy and communities (Olson, 2000), and individuals within states. Such studies naturally invite broader theorizing and should help religion and politics engage social theory of wider interest.

Abstract

The intersection of religion and science has been both more complex and less conflictive than is frequently depicted by those who cite the trial of Galileo, the dispute over the theological implications of Charles Darwin's theory of evolution by natural selection, and the Scopes trial as evidence of the historical incompatibility of religious beliefs and science. This article suggests that a complexity thesis better accounts for the relationship than the more familiar conflict thesis. It surveys the history of the relations between religion and science in the Western tradition from the fifth century BC to the present, with special reference to Christianity.

The intersection of religion and sciences has been both more complex and less conflictive than is frequently depicted by those who cite the trial of Galileo, the dispute over the theological implications of Charles Darwin's theory of natural selection, and the Scopes trial as evidence of the historical incompatibility of religious beliefs and scientific endeavor. This article will first examine the conflict thesis, and then survey the history of the relations between religion and science in the Western tradition from the fifth century BC through the first decade of the twenty-first century with special reference to Christianity.

The Historiography of Religion and Sciences

The thesis that Christianity has been historically hostile to science was popularized by two influential works that appeared in the late nineteenth century: John William Draper's (1811–82) *History of the Conflict between Religion and Science* (1874) and Andrew Dickson White's (1832–1918) *A History of the Warfare of Science with Theology in Christendom* (1896). White argued that Christianity had a long history of opposing scientific progress in the interest of dogmatic theology. Wedding a triumphalist view of science to a dismissive view of theology, his thesis struck a responsive chord in American thought, which was at the turn of the twentieth century increasingly committed both to a secular outlook and to recognizing the central role that the sciences played in modern society. The Draper–White thesis amplified a positivist outlook, viewing science as continually progressing and overcoming the entrenched antagonism of religious opinions, which invariably retreated before its advance. This thesis became enormously influential in the United States both among academics and in the popular mind.

Some historians regarded the Draper–White thesis as oversimplifying and distorting a complicated relationship. Thus, Burtt (1932) suggested that, far from being hindered by religion, science was in fact indebted to theological ideas. Alfred North Whitehead (1926) rejected the view that in controversies between science and religion, "religion was wrong, and … science was always right. The true facts of the case are very much more complex, and refuse to be summarized in these simple terms." A number of important studies by Robert K. Merton, Herbert Butterfield, and Alexandre Koyré, among others, also challenged the conflict thesis. Some historians of science went even further to argue that specific components of Christian theology were responsible for the scientific revolution. Following Max Weber and Robert Merton, some scholars argued that Calvinism's accommodationist understanding of Scripture and its voluntaristic theology encouraged scientific endeavor, and others maintained that theism encourages a belief in a rational creator, which may precondition scientific reasoning (Jaki, 1974).

Several scholars have provided a systematic reevaluation of the conflict thesis, particularly Lindberg and Numbers (1986) and Brooke (1991). Lindberg and Numbers argued for a historical picture that recognized a complex and diverse interaction that defies reduction to simple 'conflict' or 'harmony' to replace the largely polemical one drawn by Draper and White. Brooke objected to imparting essentialist understandings to words like 'science' and 'religion,' which had many different meanings over time and could not be reduced to simple static concepts. 'Natural philosophy,' for example, denoted something very different in the seventeenth century from 'science' in the twentieth. The growing acknowledgment that in their relations, religion and the sciences have exhibited a multiplicity of attitudes, reflecting local conditions and particular historical circumstances, led Brooke to suggest that a 'complexity thesis' was a more accurate model than the familiar conflict thesis. The views of Brooke and of Lindberg and Numbers have gained increasing acceptance among many historians of science.

Greece and Rome

Western science as an explanatory enterprise began with the Greeks. It was in the sixth century BC that pre-Socratic philosophers like Thales (fl. 585 BC), Anaxagoras (*c.* 500–428 BC), and Anaximander (610–546 BC) challenged the mythopoeic picture of the natural world. The pre-Socratics understood the world in nonmythological terms, viewing it as the product of natural forces. In the late fifth century BC, they experienced some popular opposition in Athens. In *c.* 437–436 BC, Anaxagoras was prosecuted on a charge of impiety and his books publicly burned.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.84030-1

By the end of the fifth century BC, natural philosophy (physical science) had come to be recognized by the Greeks as offering the most suitable means of understanding the world of nature, and religious issues played a limited role in either hindering or encouraging scientific endeavor in the classical world after that time. This does not mean that religious ideas were of no account in formulating worldviews for the Greeks or for the Romans, who took over the philosophical and scientific culture of the Greeks. The Epicureans explicitly repudiated a religious view of the universe, while for the Stoics, science (especially cosmology) and religious thought were intimately related. Moreover, the Greek view of the world was predominantly an organicist or vitalist one. Philosophical naturalism, which was espoused by the pre-Socratic philosophers, the sophists, Aristotle (384–22 BC), and the Epicureans, always remained a minority opinion in Greco-Roman thought. In general, the Greeks conceived of nature as a divinity. Plato (*c.* 427–347 BC) believed that a world soul (*psyche*) animated the universe, in which the sun, the moon, the stars, and the planets were gods. A vitalist world picture, stripped off its pagan elements, was transmitted by the Romans to Western Europeans, who continued to hold it well into the Middle Ages.

Late Antiquity and the Middle Ages

Christianity spread rapidly throughout the Roman Empire owing to its extensive missionary activity. In the second century AD, Christian apologists (theologians who defended their faith philosophically against pagan critics) began the process of harmonizing Christian revelation with Greco-Roman philosophy. Apologists like Justin Martyr (*c.* 100–65), Tertullian (*c.* 160–220), and Irenaeus (*c.* 130–200) held ambiguous positions on natural philosophy. While they often denounced it for its pagan religious or anti-Christian elements, they employed its methods, thought forms, and vocabulary – and drew on it when it was useful in the rational defense of Christianity. This hellenized Christianity by taking elements of classical culture and incorporating them into the Christian worldview. Tertullian, for example, who asked, "What indeed has Athens to do with Jerusalem? What harmony is there between the Academy and the church?" is sometimes cited as an example of early Christian antiintellectualism. Yet he often borrowed from Greek natural science and medicine to buttress his theological arguments. Not all Christian apologists accepted Greek science, whilst a few, influenced by ascetic ideals or concerns about potential demonic influences, were hostile in their approach to Greek pagan natural philosophy.

Augustine of Hippo (354–430) shared the reservations of some of the apologists about the value of natural philosophy, but he recognized its utility. Like other apologists, he rejected *curiositas*, the desire to pursue knowledge for the sake of knowing, which he regarded as a characteristic feature of pagan learning. But Augustine believed that the study of natural philosophy was legitimated when it served higher purposes, such as aiding in the understanding of Scripture or lending support to Christian theology. By becoming the handmaiden of Christian theology, natural philosophy was assured a place in the emerging Christian culture, one that was to last through the Middle Ages and well into the early modern period.

The early Middle Ages (*c.* 500–1000) was a period of disintegration that followed the collapse of the Roman Empire in the West under repeated attacks and occupation by Germanic tribes. As towns became villages, public services ceased to exist, and roads became impassable, the cultural continuity with the classical world was nearly severed. Educational institutions disappeared, and learning in the West was confined to Christian monasteries. A few scholars attempted to preserve natural philosophy during this period, including Cassiodorus (*c.* 485–580); Isidore, bishop of Seville (*c.* 560–636); the Venerable Bede (*c.* 673–735); and John Scotus Erigena (*c.* 810–77), but they did so as clerics, within a monastic framework, and with the confidence that scientific knowledge, as a handmaiden to theology (*philosophia ancilla theologiae*), was worthy of being transmitted to future generations.

The eleventh and twelfth centuries experienced the revival of trade between western Europe and the eastern Mediterranean, together with the concomitant renewal of urban life, the growth of manufacturing, and the beginning of the gradual transformation of Europe from a rural to an urban economy. Cathedral schools sprang up in cities and gradually replaced monastic schools. In the twelfth century, natural philosophers avidly studied Plato's *Timaeus* and attempted to harmonize its *cosmology* with the Creation account in Genesis. The Arabs had preserved Greek learning, and works by Greek authors on natural philosophy were translated into Latin from Arabic, thus making available much new scientific material. Muslim contributions (e.g., in optics) were significant as well.

There was much in Aristotle's writings that was useful to European Christians, but there were also areas of potential conflict, such as Aristotle's belief that the world is eternal, that the soul is not immortal, and that the universe can be accounted for by naturalistic and even deterministic explanations apart from divine providence. These and other incompatible doctrines caused the teaching of Aristotle's natural philosophy to be banned from the University of Paris in 1210 and 1215, but by 1255 his writings had gained official sanction, and they came to be widely studied. A number of distinguished scholars, including Roger Bacon (1213–91), Albert the Great (1200–80), and his student Thomas Aquinas (*c.* 1224–74), attempted to create a synthesis of Aristotelian philosophy and Christian theology that would reconcile the Christian faith and classical reason. The existence of a more radical faction at Paris, headed by *Siger of Brabant* (*c.* 1240–84), led the bishop of Paris, Etienne Tempier, to condemn, at the request of traditional theologians, many of the philosophical propositions espoused by Siger. The condemnations represented a conservative backlash that placed limits on speculation in natural philosophy. In the long run, however, they provided incentives to explore other scientific options that lay outside Aristotelian natural philosophy, particularly by way of thought experiments that entertained hypothetical possibilities, such as the existence of other worlds or of a vacuum.

The Copernican Revolution and Galileo

The geocentric theory of the solar system, as refined by Ptolemy of Alexandria (second century AD), was almost universally accepted in the West and taken to be compatible with their

theology by Jews, Muslims, and Christians until the seventeenth century. The first major challenge to the Ptolemaic theory came with the publication of Nicolaus Copernicus' (1473–1543) *De revolutionibus orbium coelestium* (*On the Revolutions of the Heavenly Bodies*), which appeared after the author's death in 1543. Copernicus advocated a heliocentric model of the solar system, and was encouraged to publish it by the Lutheran astronomer Georg Rheticus (1514–74); and while Lutherans at the *University of Wittenberg* initially rejected heliocentric cosmology, several, including Philip Melanchthon (1497–1560), were attracted to the mathematical convenience of the new theory. However, most natural philosophers rejected heliocentrism, and in 1600 there were probably no more than 10 Copernicans in all Europe.

One scientist who was quick to embrace the new theory was *Galileo Galilei* (1564–1642), a young professor of mathematics at the University of Padua. Although secretly a Copernican by 1597, Galileo did not publicize his views until 1613, when in *Letters on Sunspots* he declared his acceptance of the heliocentric system. It was, however, his *Letter to the Grand Duchess Christina* (1615), in which Galileo argued that Scripture did not intend to impart scientific truth but accommodated itself to popular language in describing the natural world, that provoked the Catholic Church's response. Although a layman, Galileo had undertaken to interpret the Bible. In the following year (1616), he appeared before the Congregation of the Holy Office (the Inquisition). The Church declared the theory 'false and contrary to Holy Scripture' and recommended that *De revolutionibus* be 'suspended until corrected.' Galileo was warned not to teach or defend heliocentrism. In 1632, Galileo published his *Dialogue on the Two Principal World Systems*, an ostensibly even-handed debate between proponents of the Ptolemaic and Copernican theories in which the arguments for the Ptolemaic theory were made to look feeble. Galileo was summoned to Rome, where he stood trial in 1633. Compelled to abjure his belief that the earth moved, he was confined to a country estate until his death in 1642. The strong reaction against Copernicanism (and Galileo's espousal of it) came from the Aristotelians of the scientific establishment, some of whom were determined to entangle Galileo with the Church. In particular, Galileo aroused the ire of a loosely organized movement of traditional scientists called the *Liga*, which succeeded in introducing theological issues into scientific discourse and attacked Galileo for his views. The Church was also spurred by the Protestant Reformation to prove its good faith in interpreting Scripture literally in the face of Protestant attacks on its allegorizing tendencies in biblical exegesis. Aristotelianism became, in its Thomistic form, a rigid dogma, and the papal court became, after the Council of Trent (1545–63), more authoritarian. The Inquisition and the Index of Prohibited Books, introduced into Italy by forces of the Counter-Reformation, were employed against Galileo.

The Mechanical Philosophy and Natural Theology

By the mid-seventeenth century, the Copernican theory had come to be widely accepted, and a mechanical model of the universe was formulated to account for all natural phenomena in terms of matter and motion without reference to action at a distance. The mechanical philosophy had its roots in corpuscular materialism, which explained physical phenomena by the interaction of tiny particles of matter called atoms. While elements of the model had been adopted by several of the leading figures of the scientific revolution, its most influential advocates were René Descartes (1596–50) and Pierre Gassendi (1592–55), who sought to devise a new philosophy that would replace Aristotelianism. While Descartes and Gassendi grounded their mechanical philosophies in theological considerations, critics feared that their views would lead to materialism, as they did in the case of Thomas Hobbes (1588–1679), or to deism, as they did in the case of Voltaire (1694–1778).

Mechanical philosophy received its greatest synthesis at the hands of Isaac Newton (1642–1727) in his *Principia Mathematica Naturalis Philosophiae* (*Mathematical Principles of Natural Philosophy* (1687)). By his discovery of the principle of universal gravitation, Newton succeeded in harmonizing celestial and terrestrial mechanics, bringing for the first time the whole of nature into a precise rational interpretation. Newton's picture of a universe governed by uniform laws that could be described without recourse to primary causes resulted in the widespread belief that nature was self-governing, and aided the 'natural religion' of deism and its idea of a 'watchmaker' God. On the basis of his synthesis of the mechanical philosophy, David Hume (1711–76) developed a materialistic philosophy in England, while in France philosophers like Julien Offray de La Mettrie (1709–51) and Baron d'Holbach (1723–89) embraced atheistic materialism.

The popularity of the mechanical philosophy led in the latter half of the seventeenth century to the creation of a natural theology that continued into the nineteenth century. Natural theology seeks to argue for the existence and attributes of God by means of knowledge derived from natural reason rather than from special revelation. There were several grounds for its attraction: the wonders of scientific discoveries, many of which could be seen for the first time with the invention of the microscope; the desire to secure an adequate foundation for a theology of divine providence that would confront the perceived dangers of materialistic atheism; and the enormous influence of Newton's mechanical picture of the world. The argument from design became the cornerstone of a natural theology, in which God was described as a craftsman, a geometer, or an architect. Natural theology reached its apex in William Paley's (1743–1805) influential *Natural Theology, or Evidences of the Existence and Attributes of the Deity* (1802).

Geology and Darwinian Evolution

The influence of the Enlightenment, with its exaltation of reason and rejection of special revelation, can be observed in the developments that were occurring in science, particularly in the increasing tendency to seek naturalistic explanations and to divorce science altogether from theological considerations. In the seventeenth and eighteenth centuries, theories of the earth had sought to weave together geology and theology in what was termed 'physico-theology.' Many of these theories calculated the age of the earth by using biblical chronologies in a way that could be harmonized with physical principles. Invariably, they postulated a young earth. While most

attributed organic fossils to the Noachian Flood, by the eighteenth century it was becoming increasingly difficult to explain the global distribution of fossils by a single event (the Deluge) that had taken place a few thousand years ago. The French naturalist *Georges Louis Leclerc, Comte de Buffon* (1707–88), a deist, proposed a much older earth, publicly of 75 000 years and privately perhaps as old as 3 million years, and suggested that each of the six biblical days of Creation might correspond to an immense length of time. Georges Cuvier (1769–1832) demonstrated the existence of fossil mammals unlike any in his own day, and argued that a series of geologic catastrophes had eliminated species in past ages. Cuvier's catastrophes were not global and in his case did not derive from his Christian convictions. But they were later read as such and were appropriated in English natural theology to support catastrophism, which became a popular form of physico-theology that attributed geological changes to great catastrophes of the past, the most recent being the biblical Flood.

The Scottish geologist Charles Lyell (1797–1875) rejected providential interventions in geologic history. In his *Principles of Geology* (3 vols., 1830–33), he succeeded in severing geology from theology. Lyell rejected diluvialism (catastrophism) for what became known as uniformitarianism: the theory that geological changes on the earth's surface have occurred slowly over long periods of time and that in explaining change we refer to processes that we currently observe. Previous proponents of *diluvialism*, like William Buckland (1784–1856) and Adam Sedgwick (1785–1873), quickly abandoned catastrophism and adopted the new geology, which Christians harmonized with the Genesis account of Creation in a relatively painless fashion. A group of laymen who called themselves Mosaic or Scriptural geologists continued to take their geology from Genesis, but they were marginalized since nearly all professional geologists abandoned the Noachian Flood as an organizing idea in accounting for changes in the earth's history.

Charles Darwin (1809–82) had, as a young man, been strongly influenced by Paley's natural theology. During his voyage aboard the H.M.S. *Beagle*, however, he read Lyell's work and began to think that slow changes had produced the geological phenomena that he observed. His theory of evolution by natural selection, published in *Origin of Species* (1859), made use of Lyell's theories that the earth was very old and the fossil record is imperfect. Evolutionary ideas had preceded Darwin. Originating in the Enlightenment, they had already been proposed in the eighteenth century by Charles's grandfather, Erasmus Darwin (1731–1802), and by Jean-Baptiste Lamarck (1744–1829), the latter proposing the theory that acquired characteristics were inherited. By the mid-nineteenth century, the belief that transmutationism (evolution) represented a divine plan was widespread. In advancing natural selection as a mechanism for evolution, Darwin argued that in the 'struggle for existence,' those individuals with even a slight advantage would survive and pass on their advantage to their offspring. Herbert Spencer (1820–1903) referred to it as the principle of the 'survival of the fittest.'

Darwin's theory met with a mixed response that cut across conventional professional and religious boundaries. Some scientists initially rejected it, while a number of clergymen accepted it. Conservative anti-Darwinists, including several leading naturalists like Louis Agassiz of Harvard (1807–73), geologists like the Canadian William Dawson (1820–99) of McGill, and theologians like Charles Hodge (1797–1878) of Princeton Seminary, rejected it, fearing the break with final causes. A second group of Christians accepted evolutionary theory as compatible with a biblical faith. They included the Scot James McCosh (1811–94), president of Princeton University, and the American botanist Asa Gray (1810–88) of Harvard. A third group came to believe that evolution had rendered supernatural religion untenable and opted (most often) for some form of philosophical materialism.

By the 1870s, however, most scientists and a large body of the educated public had accepted some form of evolution (though not necessarily by natural selection). Full acceptance of Darwin's views on human nature, as set forth in his *Descent of Man* (1871), was more difficult for Christians. Darwin maintained that moral values were rationalizations of social instincts that had developed by natural selection, thus asserting a full-blown materialism. Alfred Russel Wallace (1823–1913), the co-discoverer of the theory of evolution by natural selection, rejected materialism, maintaining that the creation of the human mind required nonmaterial forces.

In the 1920s, evolution was one of several theological issues that divided the major Protestant denominations of North America in the modernist–fundamentalist controversy. While many Protestants (as well as Roman Catholics and Jews) had come to believe in an old earth and to harmonize belief in evolution with a nonliteral interpretation of the Genesis account of Creation, conservatives emphasized in their rejection the atheistic and materialistic dangers inherent in a naturalistic theory of human origins. But the Scopes trial , held in Dayton, TN in 1925, symbolized the inability of biblical literalists to withstand the force of Darwinism, which had come to be taken for granted by the intellectual elites of Europe and America. Antievolutionism was pilloried in the American press as a rear-guard reaction to scientific progress, and it was associated with nativism and a rural and uneducated religious fundamentalism. Although biblical catastrophism was revived in the 1920s, it enjoyed favor only in conservative and sectarian Protestant circles in North America before it exploded into a popular creationist movement (called 'flood geology') in the 1960s.

Twentieth-Century Physics and Cosmology

From about 1895, modern physics began to deal with issues that went beyond those of classical physics, including quantum mechanics and special and general relativity. The introduction of quantum mechanics challenged the determinism of the mechanical picture of Newtonian physics. The central features of quantum theory were developed separately in 1926 by Werner Heisenberg (1901–76) and Erwin Schroedinger (1887–1961). The indeterminacy principle of Werner Heisenberg demonstrated that one could not know perfectly both the position and momentum of a subatomic particle. Heisenberg's principle gave rise to much discussion of its wider philosophical and theological implications. Theologians such as John Polkinghorne have argued that the

discovery that physical processes, both at the microscopic level of quantum theory and at the macroscopic level of chaos theory, are unpredictable brought about the demise of a mechanical view of the universe. Theologians argued that this offered space for God's immanence to operate through natural law in providential action, in place of the deistic belief in a God who is not involved in superintending its creation (Polkinghorne, 2005: x–xi).

Discoveries were also made in cosmology that caught the interest of theologians. Edwin Hubble's (1889–1953) discovery that the universe was expanding at a tremendous rate led the Belgian Catholic priest and physicist *Georges Lemaître* (1894–1966) to propose that the universe had begun as a dense 'primeval atom' that had exploded in the distant past. The English astrophysicist Fred Hoyle (1915–2001) dismissively termed it the 'big-bang' theory. Hoyle challenged the theory by offering an alternative steady-state theory, according to which the universe is eternal but matter is being continuously created in space. In the late 1960s, several observational discoveries led to the almost universal acceptance of the big-bang theory, which some scientists with religious convictions have argued supports the notion that the universe was created by God.

Several cosmological theories have developed to attempt to counter materialistic explanations for the origins of the universe and of humans. Among them are the anthropic principle and intelligent design (ID). The anthropic principle asserts that the emergence of human beings in the universe is not an accidental by-product of purposeless cosmic evolution. According to this theory, the universe was so finely tuned during its earliest moments that if any one of several physical parameters had been slightly different it would have been unsuitable for the creation and survival of human life. Hence, it is argued that the inhabited universe is anthropocentric, having been designed for human beings. The anthropic principle reintroduced into cosmological speculation issues that scientists had laid to rest, including questions of teleology and divine providence. Much more controversial was the ID movement that arose in the 1990s. It extended the argument from design to biology, claiming that intelligent causes are required to account for complex structures in biology and that they can be empirically detected.

Eugenics and Biotechnology

The term 'eugenics' was coined by the English scientist Francis Galton (1822–1911), cousin of Charles Darwin. The eugenics movement sought to improve the human race by eliminating mental illness, retardation, and criminal behavior through such means as compulsory sterilization and restrictions on marriage. In the early decades of the twentieth century, the movement attracted broad scientific and medical support in Europe and North America from well-known liberal Protestants who lobbied for legislation to require eugenic sterilization. Religious bodies and leading clergy in England and on the Continent supported national eugenics legislation. In 1930, Pope Pius XI, in an encyclical on marriage, condemned eugenics. In doing so, he was criticized by scientists and some Protestant clergy, who believed that scientific research supported it. Roman Catholic and some conservative Protestant opposition helped to defeat eugenics laws in several American states in which the Catholic population was large.

In the latter third of the twentieth century, biotechnology raised new ethical issues that elicited responses from religious groups. These included medical experimentation on human subjects, artificial insemination, *in vitro* fertilization, organ transplantation, cloning, and stem cell research. On genetic engineering, widespread concern existed across the theological spectrum that genetic experimentation might usurp God's creative role and that transgenic animal research and human cloning could alter the genetic makeup of humans. On the other hand, some theologians, such as Ronald Cole-Turner (1993) and Ted Peters (1997), argued that genetic engineering offered people opportunities to become co-creators with God.

Ecology and the Environmental Movement

Other scientific matters drew the attention of religious communities in the late twentieth century. Prominent was the Protestant theme (although it is by no means exclusively Protestant) of man's stewardship over nature, which involved the care of creation that God had entrusted to the human race. The duty of Christians to care for the environment, with special concern for other creatures, extended from the Puritans to John Wesley and was earlier advocated by St. Benedict (*c.* 480–543) and St. Francis of Assisi (1182–1226). It undergirded physicotheology in the eighteenth and nineteenth centuries and exploded into the ecological movement in the late twentieth century. In 1967, Lynn White Jr. famously argued that the marriage of science and technology was responsible for environmental devastation in the West and that its ideological origin lay in the Christian view that God had given man dominion over nature. The White thesis provoked considerable controversy, in which alternative explanations were offered. They included the democratization that followed the French Revolution and the concept of a limitless frontier that had influenced American history. Keith Thomas asserted that White had overestimated the influence of religion on the motivation of human behavior and that it was man's stewardship over nature, not domination over it, that was in fact a biblical theme. Indeed, in the last third of the twentieth century, many Christian churches adopted environmental concerns with enthusiasm in what David Livingstone has termed 'the greening of theology.' Ecological themes have entered Christian discourse and influenced its hymns, liturgies, and creeds, while a spate of books representing almost every religious point of view has joined the chorus of environmental concern. They include a variety of pantheistic and organicist views, such as eco-feminism and James Lovelock's Gaia hypothesis, which has enjoyed popularity.

Conclusion

By the 1940s, the modern synthesis of genetics and Darwin's theory of natural selection, which accounted for random variation by genetic mutation, made it possible for biological scientists to adopt a fully naturalistic position in both

method and metaphysics. Naturalistic evolution, it was alleged, was able to offer a complete explanation for the origin and development of the universe and for all forms of life, as well as for social factors like language, religion, and ethics. While some scholars considered materialism to be the only philosophical position capable of scientific support, this view is by no means uniform in the scientific community. The last decade of the twentieth century, moreover, saw a resurgence of interest in the relationship of religion to the sciences. This interest arose from a variety of sources both within and outside the scientific community, including those of Christian and other theistic traditions (who most often asserted the complementarity of religion and the sciences), process philosophers, proponents of New Age and pantheistic spiritualism, and non-Western religious traditions. Perhaps it reflected the widespread recognition that, for all its achievements, science does not provide ultimate answers to questions regarding the meaning of the universe and of life itself.

This article is a revision of the previous edition article by B.S. Turner, Volume 19, pp. 13136–13139, © 2001, Elsevier Ltd.

Abstract

There is a strong and well-documented relationship between religion and social stratification. Social scientists have studied this connection for decades, and the field has recently gained considerable momentum. We survey recent theoretical approaches to studying religion and stratification. We then provide an overview of some of the most important empirical contributions of contemporary literature. We focus on religion's role in shaping family processes, education, work, income, wealth, immigration, and health. We end with a discussion of nonreligious people. Our conclusion highlights gaps in the literature.

Religion and Stratification

Religion plays an important role in creating and maintaining social and economic inequality, and this relationship attracted considerable attention in the early days of social science (Durkheim (1912)1954; Sombart 1911; Weber (1905)1930). In the 1960s, researchers revived questions about religion and stratification, but the research lost momentum when debates about socioeconomic status convergence between mainline Protestants (MPs; members of a religiously liberal Protestant church, who typically do not accept the Bible literally and tend to be more socially liberal than conservative Protestants; CPs) and Catholics came to dominate the literature, and survey data at the time were unable to adjudicate competing claims (Glenn and Hyland, 1967; Lenski, 1961; Roof and McKinney, 1987). The study of religion and inequality has again begun to thrive, and contemporary research is extremely rich, both theoretically and empirically. In this article, we survey recent theoretical approaches to studying religion and stratification. We then provide an overview of some of the most important empirical contributions of contemporary literature. We focus on religion's role in shaping family processes and education, work and income, and wealth (wealth is usually defined as net worth or total assets, less total debts). We then address the important role that immigration and health play in these relationships. We end our article with a discussion of processes unique to nonreligious people. Our conclusion highlights gaps in the current literature.

Theoretical Approaches

Much of contemporary research on religion and stratification draws on the status attainment and life course traditions in the social sciences. Status attainment refers to the process by which individuals arrive at socioeconomic standing during their lives, and the status attainment approach has become one of the most widely used theoretical perspectives in sociological research on social and economic well-being. The theoretical foundation of this approach is Blau and Duncan's (1967) seminal research on occupational attainment. This groundbreaking work demonstrated that achieved status (i.e., education and prior occupational prestige) was the most important determinant of attainment (i.e., occupational prestige), even controlling for ascribed status (i.e., parents' status). An extensive literature has subsequently extended the basic status attainment model to explain educational attainment, income, wealth, and other measures of well-being, usually as a function of family background and individual traits – like education – that are acquired over time (Campbell and Henretta, 1980; Looker and Pineo, 1983). Recently, scholars of religion have shown that religious beliefs are an important part of the attainment process. Religious beliefs from both childhood and adulthood can affect the degree to which attainment of certain traits (e.g., education, family size) are important, and religion appears to be highly correlated with the likelihood that individuals attain these states (Keister, 2012).

The life course perspective is another common approach used to understand the relationship between religion and inequality. Life course research represents an important theoretical approach used to understand changes that occur in individual lives over time, and it has been used effectively to understand how religion affects inequality. Life course ideas are frequently used to understand changes that occur in individual lives over time. Research in this tradition typically approaches the individual life course as a coherent entity with 'multiple antecedent-consequent linkages that give it shape and substance' (Kerckhoff, 1993: p. 3). This starting point leads life course researchers to talk about trajectories or pathways over the lives of individuals and to mark these trajectories or pathways by the individuals' ages at key turning points (O'Rand, 1996; Warren et al., 2002). Life course research also typically assumes that there are patterns or regularities across individual life courses that can be identified, explained, and used to understand other outcomes (Kerckhoff, 1993). The notion of a life course captures the nuances and shapes of the trajectory within which religion influences status. Religious beliefs are dynamic and can either create or result from important turning points, and ideas from life course research have the potential to capture patterns in the resulting paths. In the following sections, we elaborate on how these ideas have come to shape the literature concerning religion and stratification.

Childhood Family Processes

Modern data from the United States provide powerful evidence that religious affiliation is correlated with various family processes and human capital. Childhood religion and childhood family traits, most notably family size, are strongly associated – for example, CPs, members of a religiously conservative Protestant church). CPs typically accept the Bible as the literal word of God and are more socially conservative than MPs, and Mormons (LDSs) tend to come from relatively large families. Today's adult white and Hispanic Roman Catholics (RCs) also both tend to come from large families, although white RC family sizes have become smaller in recent decades (D'Antonio et al., 2007; Keister, 2007). In contrast, MPs and Jews tend to come from much smaller families. Family size is an important determinant of adult attainment and well-being: those from larger families tend to have lower adult education levels, incomes, and wealth because larger families have fewer resources, both material and nonmaterial, to devote to children's intellectual development and education (Blake, 1989; Downey, 1995).

Adult Family: Marriage and Fertility

There are strong associations between religious affiliation and adult family processes, including marriage and fertility. Religious beliefs affect orientations toward the desirability of marriage, the age at which people should first marry, and related decisions about cohabitation (Hammond et al., 1993; Lehrer, 2004b, 2008; Mosher et al., 1992). Decisions about marriage and cohabitation, in turn, are closely linked to orientations and decisions regarding family, education, and work. In relatively conservative faiths, women are encouraged to focus on home and family activities, are encouraged to have large families, and are exposed to others who marry early and focus on home activities. As a result, early marriage may be perceived as both desirable and acceptable by members of these faiths (Lehrer, 2004b). Women in conservative faiths also tend to have low education levels, which limits job prospects and increases the appeal of early marriage (Hammond et al., 1993; Lehrer, 2004b, 2008; Mosher et al., 1992). In more liberal faiths, early marriage is uncommon, while cohabitation is relatively common, and educational and career attainment are encouraged, so early marriage is less appealing. Religion also affects the choice of spouse, including whether the couple practices the same religion (homogamy) (Lehrer, 1998; Sherkat, 2004); marital stability and satisfaction (Lehrer, 1996; Lehrer and Chiswick, 1993); and the likelihood of divorce (Call and Heaton, 1997; Lehrer, 2008). The selection of a marriage partner is often motivated by homogamy (e.g., education, background, and other traits), and religion is a critical dimension according to which people select a partner. Religious homogamy is an important predictor of marital stability and satisfaction, and religious heterogamy can be destabilizing and lead to divorce (Lehrer, 2004b, 1998). Couples who share the same religious beliefs can share spiritual experiences, participate jointly in religious observances and activities, both at home and in other settings, and can develop overlapping social relationships originating in religious groups. Religious homogamy also increases the likelihood that couples are similar on a large number of demographic behaviors and processes, including education, childrearing, work patterns, and decisions about finances.

Religious beliefs – separate from the effects of religious homogamy – can also affect the likelihood of divorce. In faiths in which divorce is explicitly prohibited, the social costs associated with marital dissolution are high, and the decision to divorce can generate severe social and spiritual consequences. Catholicism, for instance, has a well-known prohibition against divorce. Catholic doctrine regards marriage as a sacrament, and any valid marriage between two baptized Catholics cannot be dissolved (D'Antonio et al., 2007; Tropman, 2002). Until relatively recently, divorce was very rare among Catholics, adding social pressure to the spiritual pressure to remain married. Although divorce has increased among Catholics in recent decades, particularly among white Catholics in the United States, the likelihood of divorce is still lower for Catholics than for those from other spiritual traditions with comparable educations, incomes, and other demographic traits (D'Antonio et al., 2001, 2007).

Marriage and divorce are consequential for stratification outcomes. Marriage increases earnings and wealth, whereas divorce has a negative impact on fortunes, particularly for women (Waite and Lehrer, 2003; Keister, 2005). Part of the increase in wealth reflects the tendency of married couples to combine their assets and to begin treating formerly separate assets as joint property (Keister, 2005). Couples join savings and checking accounts and combine investments, they purchase homes rather than rent, and they otherwise consolidate finances into jointly owned property. Marriage allows couples to pool risks (e.g., if one person is unemployed, the other can continue working), creates economies of scale (e.g., in housing costs), and allows people to take advantage of a division of labor (Waite and Lehrer, 2003). Marriage also creates common goals (e.g., children and children's educations, home improvements and upgrades, and retirement objectives) that encourage couples to save. Early marriage reduces attainment of other outcomes such as education, but early marriage also might increase the likelihood of early saving and home ownership.

Fertility behavior is an important part of the causal processes linking religion, education, and family processes with inequality. It is well documented that religion influences orientations toward premarital sex and the onset of sexual activity, attitudes regarding birth control and the use of contraception, whether a person or couple has any children, the age at which people have their first child (i.e., age at first birth), family size, and even behaviors such as taking virginity and secondary abstinence pledges (Lehrer, 1996, 2004b; McQuillan, 2004; Sherkat and Ellison, 1999). CPs, Muslims, Hindus, and Catholics tend to have more traditional approaches to sexual activity and family formation. Some religious teachings and traditions include social and psychological rewards for having large families. In such pronatalist faiths, early fertility is approved of and even encouraged both by formal teachings and rules and through norms, and having many children can provide considerable social status (Lehrer, 2004b; McQuillan, 2004). LDS fertility

rates have been notably high in the United States, at least in part in response to such incentives (Lehrer, 2004b, 2008; Stark and Finke, 2000). Catholicism also strongly discourages contraceptive use and abortion, and Catholics have larger families than Protestants in many nations, though in the United States, white Catholics' family sizes have declined since the 1970s, while family sizes remain large among Hispanic Catholics (Lehrer, 2004b; Mosher et al., 1992). There is considerable variation in pronatalism across Protestant denominations, particularly in the United States, and CPs have strong norms that encourage large families when compared to MPs, Jews, and other religious groups.

Fertility behaviors have important effects on education, income, savings, and wealth. Having children early in life is particularly difficult because having a family can make it difficult to finish or complete schooling, makes career development more challenging, and can reduce initial saving and investing that can contribute to life-long asset appreciation (Keister, 2005). Studies have found that the timing of family formation helps to explain religious differences in educational attainment in the United States (Fitzgerald and Glass, 2008). Members of faiths in which early childbearing and large families are encouraged or are simply common generally wind up on the bottom of the stratification hierarchy.

Human Capital

There is extensive literature documenting the important role that religion plays in human capital acquisition in the United States (Burstein, 2007; Fitzgerald and Glass, 2008; Glass and Jacobs, 2005; Lehrer, 2004a; Sherkat and Darnell, 1999), and education is one of the strongest predictors of income and wealth accumulation. Table 1 shows that there are notable patterns in educational attainment according to religious groups in the United States. Educational attainment is particularly high among those raised in Jewish families: both years of education and the percentage holding an advanced degree (beyond a bachelor's degree) are exceptionally high for Jews. MPs also stand out in their educational attainments. White Catholics are similar to MPs in the number of years of education they attain, but they still lag behind in completing advanced degrees, a pattern that is consistent with knowing that education levels have only recently begun to increase for white Catholics. Table 1 also shows that CPs have relatively low educational attainment (Darnell and Sherkat, 1997; Fitzgerald and Glass, 2008; Glass and Jacobs, 2005; Greeley and Hout, 2006; Smith and Faris, 2005). In contrast, LDS respondents have notably higher levels of education, a pattern that sets them apart from other CP groups. Black Protestants (BPs; members of a traditionally African American Protestant church), black Catholics, and Hispanic Catholics report the lowest levels of educational attainment, particularly completion of advanced degrees. Americans who hold identifications with 'other religions' (mostly Buddhists, Hindus, Moslems, and Sikhs) also have high education levels.

Table 1 Childhood religion and educational attainment

	Years of education	*Having advanced degree (%)*
Protestant		
Conservative Protestant (CP)	13.2	10.7
Black Protestant (BP)	12.7	4.2
Mainline Protestant (MP)	14.3	19.5
Catholic	13.6	11.0
White	13.9	12.3
Hispanic	12.5	6.4
Black	13.4	4.0
Jewish	16.0	33.4
Other religion	14.9	25.2
No religious preference	12.7	9.5
Full sample	13.6	12.5

Total $n = 4369$.
Reproduced from Keister, Lisa A., 2012. Faith and Money: How Religious Belief Contributes to Wealth and Poverty. Cambridge University Press, Cambridge.

There are at least three reasons for the effects of religion on education. Some researchers emphasize the importance of constraints such as family background in shaping educational decisions and outcomes (Sherkat and Darnell, 1999). Others emphasize individual preferences (demand for education) and contextual or macrolevel conditions (supply of education) that determine options (Lehrer, 1999, 2004a, 2004b). Still others focus on particular characteristics of religious groups to explain patterns in educational attainment and human capital acquisition. CPs, for example, tend to be skeptical of the approaches taken in secular schools and universities that propagate secular humanist values and promote scientific investigation rather than acceptance of divine truths (Darnell and Sherkat, 1997; Sherkat, 2009; Sherkat and Darnell, 1999; Sikkink, 1999). These unique orientations contribute to low levels of education among CPs (Fitzgerald and Glass, 2008; Glass and Jacobs, 2005; Sherkat and Darnell, 1999). In contrast, particular traits have also been cited as significant factors in producing high levels of educational attainment among Jews (Burstein, 2007) and LDSs (Shaefer and Zellner, 2007). Burstein (2007) points out that cultural emphasis on pursuits in this life are important contributors to educational success for Jews. Shaefer and Zellner (2007) discuss the role played by the educational efforts of the LDSs, including a system of seminaries and Brigham Young University, in producing well-educated, committed LDS adults.

Work, Income, and Occupations

Religious commitments also impact occupational attainment and labor-force participation, and they have concomitant effects on personal and household incomes. One of the most pronounced relationships occurs between religious affiliation and gender differences in work behavior. There are important differences between men and women in various religious groups in terms of patterns of working full-time jobs. Women in more conservative religious traditions are less likely to work full time, whereas men in these groups are as likely as the general population to work full time. In the United States, white Catholic women of prior generations were more traditional and less likely than others to work full time, but today's

white Catholic women are nearly as likely as white Catholic men to work full time. Jewish women tend to work full time until their children are born; then they are more likely to stay at home while the children are young and return to full-time work after the first few years of the children's lives (Keister, 2012).

Although researchers have largely ignored the role that religion plays in shaping occupation and income, recent evidence shows that there are important connections. In the United States, CPs have the most low-prestige occupations, even relative to their low rates of education attainment. White RCs are moving into occupations that put them close to parity with MPs, a pattern that would have been unheard of in prior generations. At the other end of the spectrum, Jews and nonreligious people have considerable occupational advantages (Sherkat, 2012). Similarly, religion has important effects on income. Because religion is correlated with family background, adult family processes, human capital, work, and occupation, it is no surprise that many of the same patterns hold in the relationship between religion and income. CPs, BPs, and Hispanic RCs tend to have relatively low income, are more likely than others to have been raised in poverty (i.e., to have household incomes below the poverty line), are more likely to be in poverty as adults, are more likely to receive government transfer payments, and are more likely to experience extended spells of unemployment (Keister, 2012). In contrast, white RCs, MPs, and Jews have significant advantages in each of these dimensions (Keister, 2012). These findings are consistent across studies (Lehrer, 2010; Steen, 1996). Research shows that the ranking holds when various individual and family traits are controlled for, particularly the magnitude of the Jewish advantage (Lehrer, 2010; Steen, 1996).

Wealth: Assets and Debts

Wealth ownership is one of the most important components of social and economic stratification, and researchers have shown that wealth inequality is extreme in the United States. Wealth, or net worth, is total household assets less total liabilities. Wealth is relatively enduring – both within and across generations – and it is related in some way to most other measures of achievement. Wealth can enhance educational attainment, occupational opportunities, political power, and social influence. Religious groups with higher concentrations of wealth can solidify their advantages over other groups, and members of those groups will be better suited to deal with income interruptions, medical emergencies, and other crises such as war, accidents, and natural disasters. Wealth can create more wealth when it is reinvested, and it can generate income in the form of interest or dividends. At high levels of wealth, the income it generates can make paid employment unnecessary. Yet even a small amount of savings can improve security, mitigate the effects of job loss and other financial shocks, and improve well-being dramatically.

Religious commitments help to stratify societies in terms of wealth through their impact on the attainment processes described above, and religion appears to affect wealth ownership directly. In the United States, the resulting patterns are quite pronounced. CPs, BPs, and Hispanic RCs have very low levels of total net worth, real assets (e.g., tangible assets such as the home and other real estate), and financial assets (e.g., relatively liquid assets, such as stocks, bonds, mutual funds, and bank accounts), and they are very likely to have zero or negative net worth. In addition, members of these groups tend to accumulate assets relatively slowly across the entire life course, and they rarely enter high levels of the wealth distribution. In contrast, white RCs, MPs, and particular Jews are much more advantaged on each of these measures. Table 2 shows the extent of net worth differences by religious affiliation in the United States.

Immigration

Religion plays a particularly important, and theoretically interesting, role in the lives of immigrants, and religious stratification is very often a product of the variable fortunes of immigrants from different parts of the world. Social scientists in the United States have paid particular attention to religion's role in immigrant assimilation into the host country, with an emphasis on post-1965 immigrants using religion to navigate the transition process and achieve economic mobility (Hagan and Ebaugh, 2003; Hirschman, 2004). Immigrant religious organizations may also be important because they can facilitate cultural assimilation by simultaneously functioning as cultural havens and as acculturation resource centers. These organizations can ease the shock of entry into a new culture by providing space for the expression of immigrant customs, language, and group solidarity. At the same time, they can facilitate incorporation by providing resources for adapting to the new culture and navigating the naturalization process (Warner and Wittner, 1998). Similarly, religious participation can facilitate economic incorporation. Immigrant congregations often offer classes that help immigrants develop language skills, acquire professional certifications, and obtain work permits. They also provide immigrants with opportunities to develop leadership skills, build self-confidence, and expand their social networks, all of which can facilitate their searches for employment (Connor,

Table 2 Religion and wealth: median net worth

	Median net worth ($)
Protestant	
Conservative Protestant (CP)	53 800
Black Protestant (BP)	8000
Mainline Protestant (MP)	145 250
Catholic	141 500
White	333 219
Hispanic	187 188
Black	91 438
Jewish	392 500
Other religion	64 200
No religious preference	70 000

Total $n = 4369$.
Reproduced from Keister, Lisa A., 2012. Faith and Money: How Religious Belief Contributes to Wealth and Poverty. Cambridge University Press, Cambridge.

2011; Foley and Hoge, 2007). Although religion's role in facilitating incorporation can promote religious participation among first-generation immigrants, there is an ongoing debate regarding the long-term effects on immigrants. Commitments to religion may well foster segmentation rather than acculturation, and this may hinder attainment processes, perhaps especially for women brought up in patriarchal religious traditions.

Health

There is considerable evidence that religious involvement promotes both physical and mental health (Chatters, 2000), which could, in turn, influence educational, occupational, and wealth attainment. Scholars point to the social and psychological resources acquired through religious participation to explain this robust relationship, and they argue that religion affects health by operating through these resources. Being involved in a religious congregation can provide health-promoting social resources. Although social isolation can increase the risk for morbidity, people who attend religious services on a regular basis tend to have larger social networks and stronger network ties, which reduce the risks for social isolation and increase the opportunities to receive social support (Connor, 2011; Ellison and George, 1994). Despite the numerous health benefits associated with religion, religion can also undermine health. Some religious groups discourage seeking professional health care assistance, and some religious teachings proscribe specific medical procedures that are designed to promote health. Furthermore, religious belief can adversely affect health by producing serious psychological strain in adherents who wrestle with religious doubts or guilt (Krause and Wulff, 2004).

Nonreligious People

The number of nonreligious people has grown in most nations of the world, prompting scholars to look closely at this unique group who are often called 'nones.' Between 1990 and 2010, the number of people claiming no religious preference in the United States increased from 7 to 18%. In general, those who reject religious identification are more educated and also more likely to hold professional occupations and to earn higher salaries, particularly when compared to members of conservative religious groups. In the United States, those who reject religious identification are on par with MPs and white Catholics in terms of status attainment (Sherkat, 2012). However, it is unclear whether nonidentification is as strongly linked to stratification outcomes in nations where secularism is more common. Further, in highly religious nations with less meritocratic stratification systems, failure to identify as a religious person may have a negative impact on educational attainment, occupational attainment, and wealth accumulation. Finally, there is an important social-scientific question about the relationship of the association: does nonidentification or secularity promote attainment, or do education, income, and wealth motivate individuals to disavow religious commitments?

Conclusion

Renewed interest in religious stratification has led to several theoretical and methodological developments that have improved scholars' understanding of how religion creates and maintains social inequality through its influence on dynamics, such as family processes, human capital acquisition, occupational attainment, household income, wealth accumulation, immigrant transition, and health-related behavior. Scholarship in this area could be advanced by combining social capital and social network theory to analyze how the content and structure of networks interact to with religious social ties to affect attainment. Further, measures of religiosity are often limited to broad categories of identification, whereas the impact of religious beliefs over the life course is less well developed. This is particularly true for religious commitments and beliefs outside of the European Christian tradition. Most of the research into stratification and religion has used samples from the United States, and more comparative research is needed. A particularly exciting area of inquiry is the potential impact of religion on stratification for immigrants in Europe, where there has been a large influx of immigrants from Muslim nations. Until recently, widespread use of these approaches had been hindered by data limitations; however, as data sets have begun to include reliable social-network information and comprehensive measures of religiosity along with attainment-related variables, scholars now have the opportunity to explore more thoroughly the complex relationship between religion and social stratification.

Abstract

The study of religion and youth continues to grow and improve, fostering the development of new theories and data. Research on youth and religion generally fits six themes: (1) trends in religiosity and spirituality; (2) how religious or spiritual identity develops and changes; (3) how social networks, institutions, and contexts both shape and are shaped by youth religiosity and spirituality; (4) youth agency in the development of their religious or spiritual identity; (5) the degree to which religiosity or spirituality promotes well-being and prevents risky behavior; and (6) when religion has negative consequences for youth. In this article, I discuss theories, current knowledge, data, and methods common to these themes.

The study of religion in the period of the life course considered 'youth' has unique features and challenges, because this span of life (including childhood, adolescence, and emerging adulthood) encompasses immense physical and cognitive development, along with changes in social ties, autonomy, and societal expectations. Much of the research on youth and religion falls under six main themes. First are examinations of trends in religious affiliation, beliefs, practices, and salience. Second is a focus on how religious or spiritual identity develops and changes as children become adolescents and then adults. A third focus has been on how social networks, institutions, and contexts both shape and are shaped by youth religiosity and spirituality. A fourth theme emerging is the study of youth agency in the development and maintenance of their religious or spiritual identity. Fifth, research has highlighted the degree to which religiosity or spirituality promotes health (physical and mental) and achievement as well as prevents risky behavior. And a sixth theme is the study of the negative consequences of religion for youth. This article summarizes theoretical frameworks, methodological issues, and the current state of knowledge regarding youth and religion.

What Religion, Religiosity, and Spirituality Mean for Youth

Much has been written about the definition of religion and the meaning of spirituality to all ages, especially in relation to religiosity (cf Hill and Pargament, 2003; Roof, 2003; Wuthnow, 1998). Definitions of religion often involve an aspect of organization (e.g., 'a system'), and therefore refer to an external structure (e.g., a set of beliefs or an institution) that may or may not be internalized by individuals in a variety of ways (Geertz, 1993). It is also important to recognize that religions are not passively internalized (Verbit, 1970). They are in turn shaped by the human involvement they inspire. Thus, when we talk about religion in the lives of youth, it is a social institution that both influences and responds to them in interesting ways. Being 'religious,' then, refers to some manifestation of religion, and one's 'religiosity' or 'religiousness' suggests a level of engagement or identification with religion.

There are important nuances to theory about the sources and consequences of religiosity in the lives of youth depending on which dimensions of religiosity are the focus (Pearce and Denton, 2011). And multiple dimensions of religiosity are often packaged by youth in seemingly inconsistent ways (e.g., high centrality of religion and levels of private practice, but low public religiosity), which encourages examining religiosity as more of a bricolage than a linear variable that runs from low to high. Another issue is spirituality, which has very different meanings across contexts. Some connect spirituality to alternative or Eastern religious practices like meditation and may consider it wholly distinct from organized religion. Others view spirituality as a way of practicing their religious faith in ways that eschew what is viewed as the vapid routine of religious ritual. Some Christians call their spirituality a personal relationship with Jesus Christ. Some argue that these views of spirituality share a core element: a significant, personal connection to the sacred, a divine source of meaning (Hill and Pargament, 2003). Some youth find ways to enact their spirituality on their own, but many link their personal spirituality to participation in a religious community. Only a small minority of youth in the United States identify as spiritual but not religious (8% of 13–17 year olds and 12% of 16–21 year olds) – and similar results hold in qualitative studies (Denton et al., 2008; Pearce and Denton, 2011).

Trends in Youth Religiosity over Time

Studying trends, or stability and change, in youth religiosity and spirituality over time has taken two main forms – analyzing survey data for time trends, and rich observations of particular generations that thickly describe unique practices and understandings of religiosity and spirituality in youth.

Data from the Monitoring the Future Study (Bachman et al., 2000) of high school seniors in the United States show that although general levels of religious affiliation, attendance, and importance remain relatively high, there have been noticeable decreases in all three dimensions of religiosity over time since 1976. Since that time, more youth are claiming identification other than Protestant, Catholic, or

Jewish, and more are rejecting religious identification. Both groups doubled in size, from 11 to 22% and from 7 to 14%, respectively (see Figure 1).

There has also been interesting change in 12th graders' religious service attendance. Figure 2 shows that in 1976, the modal category by far was 'once or twice a month.' In 2006, attending 'rarely' became the most common response. The percentage attending weekly or more has dropped from 41% in 1976 to 30% in 2010. The percentage never attending rose from 11% in 1976 to 21% in 2010. Studies of youth religious involvement in the United Kingdom and Australia show much lower religious participation than in the United States and more steep declines in the adolescent years and beyond (Francis and Kay, 1995; Mason et al., 2007).

The importance of religion to 12th graders has not changed as much over time as the other religion measures. As seen in Figure 3, the percentage of youth finding religion 'very important' has remained fairly steady. It was 29% in 1976 and 28% in 2010. There were spikes up to 33% in the early 1980s and late 1990s. The percentage saying either 'pretty important' or 'a little important' has declined a little over time, and there has been a sizable increase in the percentage stating that religion is 'not important,' up from 13% in 1976 to 21% in 2010.

When it comes to religious beliefs, we have less trend data to work with, but recent studies give us a good sense of the contemporary situation. Data from the first wave (2002–03) of the National Study of Youth and Religion show that 84% of American teenagers (ages 13–17) believe in God, 12% are unsure, and only 3% do not believe in God (Smith and Denton, 2005). Between four and six out of 10 American teenagers say they believe in angels, demons, divine miracles, and life after death (Smith and Denton, 2005). In comparison, Francis and Kay (1995) find that among a representative sample of 13–15 year olds attending school

Figure 1 Religious affiliation of 12th graders in the United States, 1976–2010. Monitoring the Future.

Figure 2 Religious service attendance of 12th graders in the United States, 1976–2010. Monitoring the Future.

Figure 3 Importance of religion to 12th graders in the United States, 1976–2010. Monitoring the Future.

in England and Wales, 39% believe in God and 41% believe in life after death. Mason et al. (2007) report that just over one half of the Australian youth born between 1981 and 1995 believe in God, and this is a major decrease from the 81% of their parents' generation who reported believing in God at the same age.

Crockett and Voas (2006) find a great deal of change in religiosity across generations in Britain, with young British adults being only a little more than half as religious as their parents in terms of affiliation (59%), attendance (54%), and belief (56%). Although religious change has not been as dramatic in the United States, several studies point to the unique qualities of religious identity and practice for recent generations. Flory and Miller (2008) connect the unique experiences of the 'postboomer' generation to their style of religiosity, one that incorporates a spiritual quest, often within a religious community. Their findings parallel Lytch's (2004) discovery of high levels of personal autonomy among youth heavily engaged in conventional Christian youth groups. They label the mix 'expressive communalism.'

This balance and integration of one's own individualistic search for meaning together with a deep desire to do so in the company of others are themes repeatedly underlying many examinations of the character of youth religiosity in a variety of countries with different religious landscapes (Day, 2010). The institutional locations of religious activity are not always conventional religious buildings. In a study of Scottish youth, skate parks, pubs, classrooms, and youth festivals all emerge as sites of revelation and transformation (Vincett et al., 2012). Some are established by adults looking to increase the relevance of religious practice to youth; others collectively emerge from the efforts of youth themselves desiring ways to experience their faith more authentically (Hopkins et al., 2011). Harris (2010) shows how both spiritual growth and social connection are achieved among British youth on pilgrimages to the Marian Shrine at Lourdes, France. Virtanen (2010) explains how contemporary shamanic practices in the Brazilian Amazon are a means of building and maintaining trusting relationships. And Cush (2010) shows how teenage witches and Pagans emphasize their own autonomy and search for meaning, all the while building self-esteem that helps them be proud of being 'different' and therefore making them more confident in belonging and interacting with others. When contemporary youth are religious, they emphasize faith practiced in a way that connects them to others and reinforces a sense of both belonging and meaning in their lives.

Religious and Spiritual Development and Trajectories in Youth

Another central focus of the study of youth and religion is its developmental aspect, or how religiosity and spirituality change with age regardless of the historical context. Much theory in this area focuses on the cognitive development taking place during youth and how that might correspond to how youth think about and engage in religious or spiritual matters. For years, research has suggested that religious thinking between ages 12 and 18 becomes less literal and more abstract (Elkind, 1971; Nelsen et al., 1977; Potvin et al., 1976). Hoge and Petrillo (1978) find that abstract religious thinking among adolescents is negatively associated with creedal assent and religious practice. The initiation of abstract thinking is one reason typically cited for why religious practices and strength of belief tend to decrease during adolescence and emerging adulthood.

An additional theoretical frame for the study of religious or spiritual development has been identity theory. Foundational research in this area by Marcia (1966) and Erikson (1968, 1969) stresses stages of establishing a mature religious identity. Findings in this area have been mixed because of incompatible definitions of mature religion and incomparable data (Hood et al., 2003). More recent work in this area has emphasized the interaction and hierarchy of a variety of identities, including religion, to understand how

adolescents create multifaceted identities and the extent to which religion is a salient part of that identity (Spencer et al., 1997; Vaisey, 2009). It is important that the study of religion in youth continues to draw on the most recent developments in identity theory at large to refine theory and to improve measurement (Hemming and Madge, 2012). As it becomes increasingly clear that a hierarchy of one's identities informs the consequences of each feature of identity, we should be measuring religious importance in a way that uses other social identities as reference points.

One way in which the management of multiple identities is being studied is through interview studies focused on how immigrant youth develop and integrate destination culture and expectations with their native beliefs, practices, and symbols, such as Sikh youth wearing turbans (Singh, 2010). Also, Clydesdale (2007) discusses how youth who have just finished high school in the United States manage their various identities in the midst of dramatic change and transition. He finds that they use an 'identity lockbox' in which their religiosity (among other aspects of identity) is stored away and not tinkered with given everything else that is happening.

It is commonly argued that disengagement from religion occurs most often between the late teens and early 20s (Hood et al., 2003). Factors often invoked to explain this disengagement include life transitions and cognitive-development issues (Schweitzer, 2000). Many religious institutions maintain a focus on bringing in members when they marry and/or have young children, but as the span of years between adolescence and family formation widens, more distance develops between youth and their childhood religious institutions. This all reinforces the extent to which the life course perspective is a highly useful guide for examining religious change and stability during youth. The life course perspective integrates consideration of developmental processes (i.e., trajectories) and changes (i.e., transitions) that may alter patterns of development with insight into how the social context of early adolescence and life transitions throughout childhood, adolescence, and young adulthood shape trajectories of religious involvement (Elder, 1998; Petts, 2009).

Multiple studies have suggested that the frequency of religious service attendance tends to decline between the 8th and 12th grades (Potvin et al., 1976; Benson et al., 1989; Roehlkepartain and Benson, 1993; Wallace et al., 2003). A longitudinal study of adolescents in Iowa found that while frequency of religious attendance dipped during the high school years, levels of participation in other church activities tended to rise over the same period (King et al., 1997). Smith and Snell (2009) demonstrate that the period of emerging adulthood following adolescence entails a great many transitions, disruptions, and distractions. They find that a little over one-half of emerging adults in the late 2000s in the United States remain fairly consistent in their strength of belief and practices (whether high, medium, or low). The other 40% experiences changes, mostly modest and decreasing.

One recent advance in the literature on change in dimensions of religiosity from childhood through emerging adulthood is the availability of more waves of data and the application of more sophisticated longitudinal analyses such as growth curve or trajectory models (Desmond et al., 2010; Smith and Snell, 2009). Using group-based trajectory modeling, Petts (2009) finds six common trajectories in religious participation from ages 10 to 25. The three stable trajectories are those who attend weekly all along (3%), those who attend occasionally all along (23%), and those who never attend (7%). The three patterns of change are those who experience gradual decline in attendance (26%), those who experience early decline (16%), and those who experience late decline (24%). Although about one-third of youth maintain a relatively stable level of religious participation, the other two-thirds experience a decline (Petts, 2009). As more data become available, increased application of these cutting-edge statistical methods will provide useful details on the rate and timing of change in different aspects of religiosity and spirituality across childhood, adolescence, and emerging adulthood.

While the bulk of studies of religious or spiritual change in youth focus on incremental change over time (the most common type of change), dramatic religious change, often in the form of conversion or total apostasy, has drawn some interest as well. It is agreed that the peak age of conversion falls somewhere between the ages of 13 and 16 (see Gillespie, 1991; Beit-Hallahmi, 1997; Hood et al., 2003). Regnerus and Uecker (2006) find that very few adolescents in the United States experience dramatic religious change, and that personality and behavioral factors are consistent predictors of rapid decrease in religious practice and importance, while demographic, family, and peer network effects are predictive of changes in religiosity among youth.

Little is known about religious belief, practices, and meaning in childhood (Beste, 2011). This is in part due to the challenges that come in collecting data directly from children (Levey, 2009). Yet a few studies have examined qualitative data on childhood socialization (Gilkes, 2009; Haight, 2002), primarily through observational methods and parent interviews. Bales (2005) used observational methods to study children's first communion experiences from their perspective, finding that children do think for themselves, assert agency, show resistance, and have religious perspectives that are distinct from those of adults. Coles (1991) used interviews with children of all different faiths around the world to reveal how school-aged children process and express their religious and spiritual beliefs and understandings. Beste (2011) showed how children actively co-construct meaning and reality as opposed to merely absorbing and internalizing the religious teachings of adults (Beste, 2011). Rather than passively going through the motions, many second graders value this sacrament because it provides a concrete way to feel forgiven by God and absolved of wrongdoing (Beste, 2011). Researchers have tended to ascribe agency more to adolescents experiencing a higher level of cognitive development, but clearly the study of religious development could further benefit from a focus on younger children.

Agents of Religious Socialization and Youth

A major line of research in the area of religion and youth is the importance of influential others in shaping one's religious beliefs and practices, otherwise known as religious

socialization theory (Sherkat, 2003). When it comes to the religious socialization of youth, we most often think of parents and peers. Studies repeatedly find parents to be the most important religious influence in the lives of youth (e.g., Cnaan et al., 2004; Pearce and Denton, 2011; Smith and Denton, 2005; Spilka et al., 1985). And there is considerable research identifying the impact of peers on religious commitments (Desmond et al., 2010; Gunnoe and Moore, 2002; Regnerus et al., 2004). Social institutions are also important for religious socialization, and considerable research has examined the importance of educational institutions and religious organizations for influencing religious commitments (Sherkat, 2003).

From childhood through emerging adulthood, one's religious affiliation is highly correlated with the tradition in which one was raised (Sherkat, 1998; Smith and Snell, 2009). Religious beliefs and practices are also closely associated with those that parents modeled and encouraged during childhood (Gunnoe and Moore, 2002; Ozorak, 1989; Smith and Denton, 2005; Wuthnow, 1998). When parents cultivate an understanding that the family attends religious services, youth tend to believe they should attend (Lytch, 2004). Having religious parents makes one less vulnerable to dramatic religious declines during youth (Regnerus and Uecker, 2006). Furthermore, any decline in youth religiosity happens later for youth whose parents provide consistent religious messages (Petts, 2009). Although both parents matter, studies suggest that mothers' beliefs and practices are more influential than fathers' (Acock and Bengtson, 1978; Benson and Eklin, 1990). Research suggests that religious socialization tends to be most successful when families are close and relationships are harmonious, when youth live with two parents, and when parents share the same religious affiliation, beliefs, and practices (Myers, 1996; Petts, 2009; Sherkat, 1991). Part of how religious parents influence their children is by encouraging them to choose more religious peers and be involved in religious institutions (Erickson, 1992; Sherkat, 2003). The influence of religious socialization from parents takes on special importance in the case of immigrant families, in which immigrant or second-generation youth must contend with multiple cultures and identities (Warner and Williams, 2010). Not surprisingly, socialization and religious influence do not just work in one direction. Children also influence their parents. Sherkat (1991) finds that there are reciprocal relationships between parent and child religious participation and belief from childhood through adulthood.

Peers also play a role in the socialization of religious commitments; since much of youths' lives are spent in educational or extracurricular activities segregated by age, their identities evolve in some measure according to what they perceive as acceptable to their peers. When it comes to peers and religion, having schoolmates or peers with higher levels of religious affiliation, belief, practice, and salience is, not surprisingly, related to higher levels of these dimensions of religiosity in youth (Desmond et al., 2010; Gunnoe and Moore, 2002; Regnerus et al., 2004). Also, having more religious schoolmates and peers is protective against dramatic religious decline and apostasy (Regnerus and Uecker, 2006). Pearce and Denton (2011) find that adolescent peers do not report talking to each other about religion much, so either less direct methods of socialization are occurring, or these associations may be spurious, explained by other characteristics that peers tend to have in common.

Schools

Studies have found that, independent of any influence that peers have on each other, the religious composition of one's whole school is related to an individual student's religious affiliation, beliefs, and practices and to changes in these over time (Barrett et al., 2007; Regnerus et al., 2004; Regnerus and Uecker, 2006). Other research has focused on parochial education and how such experiences shape youth religiosity and spirituality, and most studies find a positive effect of religious education on religious commitments. Ethnographic studies of fundamentalist Protestant schools find that a major objective is to shelter children from the secular world, to 'keep them out of the hands of Satan' (Peshkin, 1986). Much research has focused on Catholic schools, and these studies show that the number of years of Catholic schooling is positively related to a range of proreligion beliefs and practices (Greeley and McCready, 1976; Greeley and Rossi, 1966; Guerra et al., 1989; Uecker, 2008). Youth who enrolled in Protestant schools or were homeschooled had similar levels of involvement in their local congregation as youth who attended public schools (Uecker, 2008).

Another line of research considers how college experiences shape religiosity in emerging adulthood. Sociologists of religion have long linked educational attainment to religious decline (Sherkat, 1998). However, one recent study contends that emerging adults who do *not* attend college are the most likely to curtail religious commitments in early adulthood (Uecker et al., 2007).

Religious Institutions

A few studies have examined features of religious congregations across a variety of denominations to identify features that promote religious commitment (Benson and Donahue, 1990; Benson and Eklin, 1990; Kelly et al., 1986). Research finds that congregations that offer a sense of belonging, a sense of meaning based in religious principles, and opportunities to develop competencies in the transition to adulthood do best at retaining youth members (Lytch, 2004). Certain religious traditions motivate higher levels of religiosity from both youth and emerging adults. Smith and Denton (2005) find youth who identify as Latter-Day Saints report the highest levels of religiosity across dimensions, followed by conservative and black Protestants, mainline Protestants, and Catholics, with Jewish and unaffiliated teens at the lowest levels of all dimensions of religiosity.

How Personal Characteristics and Agency Relate to Religiosity

Although a great deal of attention has been paid to theorized causes of religiosity and religious change in the lives of youth, increasingly research considers the extent to which children,

adolescents, and emerging adults exercise agency in their religious identity and actions (Beste, 2011). Youth often negotiate, resist, engage with, modify, and/or reject religious ideas and practices presented to them (Hopkins et al., 2011). Some youth actively challenge the ways in which their parents had or had not tried to transmit certain views or perspectives about religion (Hopkins et al., 2011). This can result in conflict and disagreement among parents and youth, affecting parent–child relationship quality (Pearce and Axinn, 1998).

There is evidence that certain personality characteristics are associated with different levels of religious belief and practice. Risk-aversive people report higher levels of religiosity than those who like to take risks (Miller and Hoffmann, 1995). Miller and Stark (2002) suggest that risk proclivity alone may account for gender difference in religiousness. Other personality features, such as having a strategic or planful orientation, may be at work as well. Regnerus and Smith (2005) found that strategic adolescents are significantly more likely to attend religious services frequently and report religion as being very important. Studies of genetic and birth order influences on religiousness are illuminating and invite further the study of genetic roles in religious and spiritual identity and practice (Heath et al., 1999; Saroglou and Fiasse, 2003; Bradshaw and Ellison, 2008).

Another way in which youth may exercise agency is to choose to limit or dissolve their religious identity when other identities or preferences conflict with what their religious faith prescribes. In the case of youth, it is often premarital sex, drinking alcohol, or substance use that becomes at odds with their religious beliefs and practices (Benda and Corwyn, 1997; Regnerus and Uecker, 2006; Thornton and Camburn, 1989; Thornton et al., 1992).

The Effects of Religion

Another common approach in the social scientific study of religion is to study ways in which religion may or may not be healthy or protective in the lives of young people. Research has focused on prosocial behaviors, subjective well-being, and risk behaviors in the lives of children, adolescents, and emerging adults.

Parent religious affiliation, beliefs, practice, and salience have all been linked to variance in parenting styles and methods of discipline (Bartkowski, 1995; Ellison and Sherkat, 1993; Wilcox, 2004), and therefore child outcomes (Bartkowski et al., 2008). When parents share the same religious affiliation, children have higher levels of behavioral, emotional, and cognitive development, but when parents argue about religious matters, children's developmental outcomes are lower (Bartkowski et al., 2008). Some studies have focused on how religiosity is related to the internalization and externalization of problem behaviors in children (Kim, 2008; Petts, 2011).

In studies of adolescents, their own religious beliefs, practice, and salience are often shown to be positively related to overall subjective well-being (Benson and Donahue, 1995; Markstrom, 1999), positive life attitudes, satisfaction, and hope for the future (Francis and Kay, 1995; Smith and Faris, 2002a,b), sexual behavior (Regnerus, 2007), as well as a host of other normative outcomes. Religion may provide a variety of developmental assets that lead to these positive associations, such as social support from family, friends, and nonrelative adults; empowerment; clear boundaries and expectations; having constructive uses of time; commitment to learning; positive values; social competencies; and positive identity, which likely mediate the influence of religion (Benson et al., 1997; Benson et al., 2012; Roehlkepartain, 1998; Scales et al., 2003; Smith, 2003; Wagener et al., 2003).

Of course, the positive effects of religious institutions depend on an assumption that religious communities are composed of positive interactions and role models. This is not always the case. Evidence suggests that religious adults and institutions often socialize girls to limit their educational and career aspirations and planning in anticipation of wife and mother roles that may or may not come to fruition or take up as much of the life course as expected (Pearce and Halliday, 2012). Heynes (2010) demonstrates that it is predominantly male heroes that are represented in religious education materials and that girls notice. Therefore, the benefits theorized to accrue from religious institutions may advantage boys more than girls.

A Note on Race and Ethnicity, Class, and Gender

There are three other social statuses or identities that rival, if not surpass, the salience of religion in the lives of youth: race or ethnic identity, social class, and gender identity. Most of the survey or quantitative research cited here looks at differences across these groups or at least 'controls' for them in regression analyses. Usual findings are that minority groups tend to exhibit higher levels of religiosity across a variety of dimensions, that there are class differences in denominational affiliation but few discernable patterns in practice or belief, and that girls tend to be more religious across dimensions than boys. These are all differences noted in adult studies as well, so they are not particularly insightful findings for the unique experience of religion or spirituality in youth. Studies involving more ethnographic methods such as observations and/or interviews are able to focus on certain subgroups within these statuses, delving deeper to provide rich detail on experiences, but few existing studies of youth and religion tackle the intersections of these identities (Hemming and Madge, 2012). As our theories expand and develop to consider the complexity of identities and how they are managed, our research questions and methods should adapt to collect and analyze empirical data that can speak to the ideas.

Future Directions

While the study of youth and religiosity has flourished in the United States and parts of Western Europe, the field is weakest in studying the religious lives of youth in non-Western countries where Christianity is not the dominant religion. It is important that our theories and methods be applied in new locales to (1) expand our knowledge to new settings, and (2) further realize the limitations and ethnocentricity of our current approaches. A great strength of the field of youth and

religion studies is the diversity of methods being applied and the growing number of studies that mix methods collecting both qualitative and quantitative data. This leads to a balance of broad versus deep research, showing us patterns in religious and spiritual beliefs, practices, salience, and experience across the globe as well as rich ethnographies opening our eyes to specific rituals, unique subgroups of the youth population, and distinctive religious institutions. Going forward, more cross-fertilization of the findings from disparate methods (whether in the same project or not) will advance the field even further. For example, we could use more ethnographic studies of youth to unpack the mechanisms through which religion either protects or limits youth well-being. To date, this stream of the research has been heavily tilted toward the use of quantitative data and analyses.

Finally, one of the most recent and potentially significant lines of research is that which illuminates the agency of youth in their religious and spiritual lives. For too long, the field has assumed a passive stance of youth, and we have much to learn by (1) continuing to develop and use methods to observe and interview children regarding their agency in religious and spiritual development, and (2) employing research methods, such as taking a phenomenological approach or employing statistical methods that carefully account for reciprocal relationships between factors typically thought to mostly influence youth rather than the other way around.

Abstract

This article traces the history of the anthropology of religion from the nineteenth century to the present. It argues that a focus on such questions as rationality and ritual was central to the emergence of the discipline. These themes, along with topics such as witchcraft, belief, language, and the body, have remained of perennial interest. More recently, focus has also been placed on the anthropologies of world religions such as Islam, Christianity, Hinduism, and Buddhism; on religion in relation to globalization and diaspora; and on cognitive approaches to the workings of the human mind.

Emergence of the Subfield

The comparative study of religion formed a central building block of anthropology as the discipline emerged in the nineteenth century and early twentieth century. In the light of social evolutionary models of human development, religious practice was perceived as providing a powerful index of the mental and moral levels of so-called primitive peoples. James Frazer's *The Golden Bough*, first published in 1890, traced magical and religious threads throughout history and weaved them into a pattern depicting the past and future progress of humanity, claiming to discern shifts from magical manipulation toward religious devotion and then ultimately in the direction of purely scientific modes of engaging the world. Inherent in Frazer's work was also a juxtaposition that has reemerged, albeit in very different form, in contemporary writings (e.g., Cannell, 2006): Christianity as an object of study but also a mode of thought that has itself framed anthropological understandings of religion, temporality, and culture.

The use of religion as a key site for the examination of human rationality permeates E.E. Evans-Pritchard's *Witchcraft, Oracles and Magic among the Azande* (1937). In contrast to Frazer's evolutionary assumptions and reliance on scattered examples drawn from around the world, Evans-Pritchard focuses on a single African case study, showing interrelations among religious, social, and political aspects of Azande life. The book assesses the logic and consistency of Azande modes of thought, and indicates how they might be translated into the understandings of a Western readership. Evans-Pritchard's implicit interlocutor was the French ethnologist and philosopher, Lucien Lévy-Bruhl, who had highlighted what he saw as the 'primitive' mind's inability to distinguish the supernatural from reality. While refuting Lévy-Bruhl's view, Evans-Pritchard's book also implies a comparison with Christianity: his discussion of Azande explanations of misfortune echoes biblical scholars' attempts to explain the presence and direction of evil in the world.

A further foundational strand in the anthropological study of religion has been the investigation of the relationship between religion and social order. In such work, the discipline's Durkheimian inheritance has come to the fore, in particular the view of ritual as expression and promoter of societal unity, alongside the more general assumption that religious ideas provide the key to socially shared categories of understanding.

Reflecting on the history of the anthropology of religion, Michael Lambek (2002: p. 4) characterizes contemporary research as drawing on a number of early sources: Franz Boas's tracing of connections between religion and language; Émile Durkheim's emphasis on the importance of the social; Karl Marx's pointing to forms of alienation, mystification, and power; and Max Weber's analysis of the place of religion in transitions to modernity.

Definitions

Attempts to produce a sustainable, universal definition of religion have prompted much debate. Not all scholars believe that a definition is possible. Saler (2000: p. ix) asserts that "Religion is a Western folk category that contemporary Western scholars have appropriated." A similarly skeptical view is maintained by Maurice Bloch, who notes (2010: p. 4): "'Religion' is a word that can only refer to a series of historically created situations which, although continually changing, have unique and specific genealogies closely linked to the Abrahamic religions… In other words religion is not a natural kind, by which I mean a category that has a basis other than that given by an arbitrary definition."

The earliest influential attempt at a definition was provided by British ethnologist Edward Tylor, himself born into a Quaker family. In *Primitive Culture*, published in1871, Tylor summed up religion as "belief in spiritual things." His characterization is terse in comparison with Durkheim's assertion in his book *The Elementary Forms of Religious Life*, published in 1912, that a religion can be seen as "a unified set of beliefs and practices relative to sacred things, that is to say, things set apart and forbidden – beliefs and practices which unite [into] one single moral community called a Church, all those who adhere to them" (Durkheim, 1912: p. 44). We see here some characteristic Durkheimian juxtapositions, such as the sacred and nonsacred, and belief balanced by practice; but also the claim that religion must be seen as linked to a social formation, a 'Church.' This definition of religion as a certain kind of object of study therefore also points toward a specific method of study: the focus is on what can be physically observed, and eschews assessment of the truth value or otherwise of any given religion.

Durkheim's depiction of social order proved highly influential for the British anthropologist Alfred Radcliffe-Brown,

who in the middle years of the century drew on such ideas in developing the notion of 'structural-functionalism' – a view of society as made up of, and stabilized by, interlocking and complementary components, including religious institutions. The emphasis on observable reality also informed Bronislaw Malinowski's stress not on the evolution of religion, but on the importance of fieldwork in discerning the contemporary societal and psychological rationale behind ritual and magic. At the same time, a Durkheimian approach still raised questions as to (1) the worth of assuming that rigid distinctions between sacred and profane existed cross-culturally, (2) the focus on order and stability as a feature of social institutions such as religion, and (3) the universality of any characterization of religion.

In the 1970s, the American anthropologist Clifford Geertz combined a Durkheimian understanding of religion as a collective social act with a more Weberian emphasis on meaning and experience. For Geertz (1973: p. 4), religion was "(1) a system of symbols which acts to (2) establish powerful, pervasive, and long-lasting moods and motivations in men [sic] by (3) formulating conceptions of a general order of existence and (4) clothing these conceptions with such an aura of factuality that (5) the moods and motivations seem uniquely realistic." Geertz's humanistic, 'interpretive' anthropology created intellectual distance from such figures as Claude Lévi-Strauss, whose French 'structuralism' focused on very broad cultural meanings divorced from the actions and interpretations of specific people.

A later period of anthropology would express worries over the cross-cultural validity but also the intellectual and cultural politics of the very act of making definitions. The best-known contributor to such debate has been Talal Asad (1993). Brought up in Pakistan, Asad spent some time working with Evans-Pritchard at Oxford before eventually moving to the United States. Influenced by Michel Foucault and Edward Said, he is acutely aware of the power relations involved in representing religion, and focuses on the need to trace 'genealogies' of both religious and secular, Western and non-Western, ways of viewing the world. For Asad, Geertz's (1973: p. 29) definition runs into problems in its attempt to capture a panhuman phenomenon divorced from particular cultural, social, and political contexts. In his view, the very act of defining must be seen as the historical product of ideologically charged, discursive processes. Similarly, the notion of religion as an autonomous activity is regarded as emerging from a unique, Western, post-Reformation history.

What, then, might be the solution to such dilemmas? Bloch (2010) turns to ritual rather than religion in articulating his comparative approach, arguing that the former can be found in all types of society, and is a specific type of modification of the way human beings in general communicate. Saler (2000: p. x) takes a more pragmatic approach, drawing in part on Wittgenstein's discussions of 'family resemblances' to argue that the different instantiations of what is called religion need not all share one feature, or a specific conjunction of features, but may possess certain overlapping similarities. In the following, I adopt another pragmatic, inductive approach, taking the anthropology of religion to be what scholars actually do, no matter what definition of the subject they endorse.

Enduring Themes

The following highlights some of the most prominent themes in the anthropology of religion that have remained topics of interest throughout the discipline's history.

Belief

Asad's skepticism as to the utility of belief as an analytical term is not unique. Malcolm Ruel points to "the monumental peculiarity" (1982: p. 100) and historical instability of Christian notions of belief. He notes that both the original Greek verb *pisteuo* and the Hebrew root *mn* express ideas of trust or confidence in an agreement, indicating a fundamentally social orientation. The noun *pistis* then acquires a special twist in the apostolic writings of the New Testament, where it is often used in the sense of being converted, denoting the 'belief' held collectively by early Christians as a common conviction in the resurrection of Jesus. Subsequently, the Protestant Reformation hinges on a stress on the inward totality of Christian belief. However, it is difficult to find equivalents to Protestant notions of belief in Judaism, Islam, Buddhism, or Hinduism.

Similar worries are taken up by Rodney Needham in *Belief, Language and Experience* (1972). Needham discusses the problems involved in discussing the statement "I believe in God" with one of his Indonesian informants, who belongs to an ethnic group called the Penan. As Needham puts the problem: "The Penan had no formal creed, and…they had no other conventional means for expressing belief in their God. Nevertheless, I had been accustomed to say…that they believed in a supreme god….Yet it suddenly appeared that I had no linguistic evidence at all to this effect" (Needham, 1972: pp. 1, 2). One of the issues that Needham touches on is crucial for much comparative ethnography: whereas Western Christianity is premised on the possibility of opting out of religious institutions or indeed denying belief, the kind of religion described by Evans-Pritchard for the Azande or Needham for the Penan is not a matter of choice for informants: it is an integral part of life.

What, however, of contexts where informants themselves maintain a strong and self-conscious sense of 'belief'? Joel Robbins (2004, 2007) examines the conversion to Pentecostal Christianity of the Urapmin of Papua New Guinea, and shows how even the apparent assimilation of Christian categories can conceal a more complex relationship to belief than might at first appear. The pigeon word 'bilip' is widely used by Urapmin, but it means something specific. For the Urapmin, Christian belief is not about mentally assenting to a set of propositions about divinity, but rather a form of trusting God to do what He promised.

Ritual

Anthropologists have often emphasized the importance of taking into account embodied, ritual activity. Alexander Henn (2008) notes that while Émile Durkheim emphasized the need to explore functional aspects of ritual in the making of human sociality and institutions, Clifford Geertz encouraged scholars to interpret rituals as akin to texts that could be 'read' by informants and analysts, and Victor Turner theorized ritual as

a dialectical process, moving between structure and anti-structure, secular and sacred. These approaches Henn characterizes as "normative," "intelligible" and "dialectic," respectively (Alexander Henn, 2008: p. 11). They share a tendency to emphasize the capacity of ritual to generate feelings of certainty and continuity. Roy Rappaport has also produced an influential discussion of ritual that sees it as primarily as "the performance of more or less invariant sequences of formal acts" (1999: p. 24). Yet, questions of how informants' interpretations relate to those of the analyst remain, including debates over how intentionality is linked to ritual.

Many analysts are still influenced by the work of a contemporary of Durkheim, Arnold Van Gennep. Van Gennep argued that ritual has particular significance during critical periods of transition in the life-cycle, such as attainment of adulthood, marriage, and death. In his view, it helps the participant to adjust to his or her change in role while also publicly announcing such a change. Furthermore, such rites follow a strikingly standard pattern across cultures, with the person's separation from everyday society followed by transition and then incorporation back into the social group, now bearing a changed social status. Turner finds particular inspiration in considering the 'liminal,' threshold-like section of rites of passage, arguing that they represent reversals of everyday structure and draw on powerful ritual symbolism, such as that of death, to symbolize the end of the old status. He notes that in Ndembu initiation rites in Zambia, circumcision of boys becomes a metaphor for killing, since it destroys the childhood status of the initiate (Turner, 1967).

Bloch (1992) is also interested in the symbolic and literal violence involved in many rites of passage, but applies a broadly Marxist frame of interpretation, highlighting the coercive powers of ritual. He agrees with Van Gennep concerning the existence of a basic grammar underlying ritual across cultures, and suggests that an irreducible core of the ritual process invokes a violent conquest of the present world by the transcendental, divine realm. Separation rites and rites of incorporation expunge the initiate's original vitality; but what Bloch calls the rebounding violence of transcendental conquest is contained in the return to everyday life, as the person is transformed from being prey into being a hunter – into a state where the powerful transcendent element inherited from the ritual dominates the person's identity. For instance, in the Orokaiva ritual involving the initiation of children in Papua New Guinea, participants are told they are dead, and are then taught to play sacred flutes and bullroarers that represent the voices of the spirits. After a time of seclusion, they return to the village, shouting "bite, bite, bite." They are now transformed beings.

Such analysis emphasizes the political implications of ritual experience in the service of order and hierarchy. More recently, in a number of influential books on the Tshidi of South Africa, Jean Comaroff and John Comaroff (1985) have analyzed ritual that involves complex forms of resistance quite as much as submission. Examining interactions between 'traditional' and Christian missionary beliefs and practices in colonial and postcolonial contexts, they show how Zionist churches have provided Tshidi with forms of identity, realized in part through new Christian idioms, which have allowed them to adapt or subvert structures of colonial and capitalist authority.

Anthropologists have worked more and more in urban and Western contexts often associated with deritualization and secularization, and with decreased need for common rites of passage to define accession to social roles. Nonetheless, the transformation and pluralization of ritual forms does not necessarily mean that they are disappearing. Tomas Gerholm's (1988) 'postmodern' view of a Hindu funeral ritual in Trinidad examines fragmentation of meaning and diversity of experience. His piece describes a ritualized tribute paid by the writer V.S. Naipaul to his deceased sister – an improvised response taking place thousands of miles away from the official funeral in the writer's country of origin, and yet still capable of carrying significance. If Gerholm suggests that it is often difficult to locate the core of ritual practice in postmodern contexts, Catherine Bell's highly influential approach in *Ritual Theory, Ritual Practice* (1992) moves the focus away from seeing ritual as an autonomous activity, and proposes instead a notion of 'ritualization' that takes into account links with strategic activities in social life in general.

Rationality

Frazer's radical move in *The Golden Bough* was ultimately to juxtapose Christianity with science, and to suggest the incompatibility of the former with the latter. More recent work has taken the opposite step of proposing that Western science has significant parallels with 'traditional' religious thinking. Robin Horton's "African Traditional Thought and Western Science" (1970) argues that African religions link causes and effects in much the same way as scientific practices. Religion in this sense can be seen as deploying spirits as explanatory principles much as a scientist might use atoms or molecules. Horton's assumption is that religion is fundamentally *about* explanation, a so-called 'intellectualist' stance toward religion that places him in the genealogy of both Tylor and Frazer. The key contrast here is with so-called symbolist approaches, which draw on a Durkheimian inheritance to emphasize how religion, and in particular ritual, should primarily be interpreted as made up of representations of the social order.

Despite such differences of opinion, the basic consensus among anthropologists is that human capacities to think are universally the same the world over. Another book published in the 1960s, Lévi-Strauss's *La Pensée Sauvage* (1966: 'The Savage Mind'), denies that non-Western mental abilities are inherently inferior to those of Western readers, even if attitudes toward abstract thought may differ.

The Body

Durkheim's and Radcliffe-Brown's functionalist approaches drew on a model of society as equivalent to a body, made up of interlinked and mutually dependent parts. Other authors in the Durkheimian school provided significant perspectives on the physical workings and symbolism of the body. Marcel Mauss, Durkheim's nephew, developed the notion of 'habitus,' the idea that certain elements of culture (habits, tastes, skills) become rooted in the body over time. Within Anglo-Saxon anthropological circles, Mary Douglas's combination of British empiricism and French structuralism resulted in some highly influential work on the function of the body as social and

religious symbol. In *Purity and Danger* (1966), Douglas (a student of Evans-Pritchard at Oxford, and like him a Roman Catholic) explored Western as well as non-Western contexts. In her view bodies, like societies, can be seen as bounded systems, whose integrity and boundaries often need to be protected. What is considered pure and impure, however, varies cross-culturally, and reflects the social experience of the social group involved. Thus in Hindu society, high-caste Brahmins and low-caste untouchables are often interdependent in economic and social terms, but idioms of purity and pollution regulate their behaviors toward each other in very specific ways – for instance, through preventing them from sharing food. A further implication of this argument is that symbols or actions that defy categories or bridge them may be seen as powerful, and under certain circumstances even sacred, rather than polluting. We see here parallels with the potent middle section of the rite of passage, where initiates are passing 'in between' statuses.

Douglas has little to say about the actual physical experiences of having a body that possesses senses and moves through the world. A leading figure in the move toward a more phenomenological view of the body has been the American anthropologist Thomas Csordas (1997), in his studies of healing, language use, and spatial orientation among charismatic Catholics in America. Csordas has presented a sense of the body as both 'self' and 'not-self,' both subject and object, but also the very grounding of the human experience of culture. Important work has also been carried out on the relationship between gendered experience and religious engagement (e.g., Austin-Broos, 1997).

Language

Language mediates much religious activity, ranging from spells to prayers to texts. Some religious language seems not merely to describe reality, but also to have 'performative' dimensions, in other words to create material or social change through being articulated by authoritative figures. An early piece by Bloch (1974) explores his interests in the relationships between ritual and authority by arguing that the religious oratory of the Merina of Madagascar is expressed in a language that is so formalized that it is difficult ever to argue against: we might compare it with a Latin Mass, for instance, or with the inauguration speech of a President.

Some of the broader issues relating to religious language are explored by Keane (1997). For him, a fundamental question is: What, if anything, is particular to religious language? He suggests that such language may raise a particular kind of problematic: the effort to know and interact with an 'otherworld' tends to demand highly marked uses of linguistic resources. In religious contexts the sources of words, as well as the identity, agency, authority, and presence of nonhuman as well as human participants in an interaction, can be especially problematic.

Witchcraft

Witchcraft has proved a resonant subject in part because it invokes many of the themes evident in other areas of the subfield. The witch represents an 'impure' challenge to social order as well as to physical well-being, and embodies some of the key anxieties of a given society. Evans-Pritchard's classic study of the Azande retains much of its power because his argument is rooted in analysis of both social relations and modes of thought. We follow Azande investigating why misfortune appears to strike certain people at certain times, while accusations are linked to tensions in relations among equals. Subsequent work on witchcraft from the 1940s onwards often examined it in the context of changing social relations and periods of communal stress.

Later work has examined the question of rationality and witchcraft under very different social conditions. Tanya Luhrmann's *Persuasions of the Witch's Craft* (1991) examines the role of witchcraft – or Wicca – among middle-class Londoners in the light of theories of the sociology of knowledge as well as of conversion. Luhrmann traces the gradual emergence of commitment to magical ideas among practitioners who have easy access to alternative modes of thought, and who may deploy very different systems of rationality in their work lives.

Some of the most recent work on witchcraft and wider notions of evil and the occult links these again with forms of anxiety rising from shifting and uncertain social, political, and economic circumstances. Meyer (1999) analyzes notions of evil in the context of the emergence of local Christianity and its relation to changing social, political, and economic formations among the Peki Ewe in Ghana. Her main argument is that, for the Ewe, the Devil forms a hybrid figure, expressing people's obsessions with occult forces as a way to mediate the attractions and discontents of modernity. Writing of the postcolonial period in South Africa but also highlighting resonances with other postrevolutionary societies, Jean Comaroff and John Comaroff (1999) explore occasions when vast wealth appears to concentrate in the hands of just a few citizens, so that the market seems to contain mysterious mechanisms of accumulation and distribution. In such contexts, they argue, disenfranchised people imagine new, magical means to attain otherwise unattainable ends, even as they mistrust those who appear to enrich themselves through illegitimate deployment of the forces of production and reproduction.

Newer Themes

Despite predictions from secularization theorists that the significance of religion would weaken around the world along with modernization, religion has retained and even increased its profile in many public as well as private contexts. To some degree anthropologists have turned their attention to secularism itself as a particular, historically constructed category. The study of religion has generated new topics and methods as well as building on more established ones.

Anthropologies of 'World' Religions

Although most anthropologists feel uneasy with the idea that so-called world religions such as Christianity, Islam, Judaism, Buddhism, and Hinduism can be regarded as autonomous systems, there has been a move in recent decades for researchers to identify themselves as ethnographers of a particular religion. This development is a result of a number of factors: the shift of fieldwork toward more

urban, plural contexts, where self-conscious religious identification is occurring; increasing interest in past encounters between Western missions and colonized peoples; a new focus on the affinities of different religious forms with 'modernity'; the relative success of Islam and Christianity as missionary forces; and the self-conscious identification of many informants with religions that have transnational, including diasporic, referents.

A major theme in the anthropology of Islam that has recently emerged relates to the emergence of 'Muslim publics' that have been energized by migration, challenges to Western hegemony, and access to new media technologies. Eickelman and Anderson (1999: p. 1) refer to the emergence of a new sense of public throughout Muslim-majority states as well as Muslim communities elsewhere. They propose the existence of a distinctly Muslim public sphere located at the intersections of religious, political, and social life, operating outside formal state control. The role of this sphere in the emergence of the 'Arab Spring' from the end of 2010 remains to be analyzed. Hirschkind (2006) focuses on the role of the cassette sermon in promoting Islamic revival. His argument that listening to sermons links to ethical self-improvement forms a bridge to another significant theme in the analysis of Islam: the cultivation of piety. Mahmood's *Politics of Piety* (2005) focuses on a women's movement in the mosques of Cairo. While members cultivate embodied practices of personal piety that appear to submit to the patriarchal logic of certain forms of Islam, Mahmood indicates how informants are motivated by dissatisfaction with both secularization and Westernization. At the same time, her analysis critiques secular liberal assumptions concerning the universality of aspects of feminist theory.

Anthropologists have studied examples of Christian worship ever since the early days of the discipline, yet it has received less attention than other religious expressions. One reason may be the ironic one that Christianity is too close to the culture of Western anthropologists, and so it was avoided or perhaps simply not noticed as a valid topic of study. More recently, the emergence of Christianity as an explicit object of study has contributed to and resonated with many current concerns of anthropology, including globalization, reflexivity, and postcolonialism. A particularly fertile strand of research has been a focus on materiality and its relationship with notions of both transcendence and modernity (Keane, 2007).

Globalization and Diaspora

Some of the most effective work in this area has looked at past processes of colonization, where religion has formed part of the tangled encounter between colonizers and colonized, 'modernity' and 'tradition' (Van der Veer, 1996). More recently, religious communities have taken advantage of, and helped to constitute, the globalization of culture. The years following World War II have seen the reemergence of evangelical forms of Christianity in many parts of the world. Although the term 'diaspora' has in the past most often been used to describe the dispersion of Jewish populations away from the land of Israel, in the last two decades in particular it has been taken to refer to the creation of large South-Asian communities in European and North American contexts (Vertovec, 2000), as well as the movement of African migrants in search of both economic mobility and the possibility of 'reverse mission' within the secularized West.

Processes of globalization and migration, combined with tourism, have ensured that pilgrimage has become an increasingly visible dimension of religious activity in all faiths, and also one that has attracted more anthropological attention. Victor and Edith Turner's seminal work, *Image and Pilgrimage in Christian Culture* (1978), which deployed a rite-of-passage model to emphasize the idea that sacred shrines should be seen as liminal spaces, has been challenged by Eade and Sallnow's (1991) argument that such shrines are in fact deeply enmeshed in everyday political and economic processes. Coleman and Eade (2004) place anthropological studies of pilgrimage in the wider frame of analyzing physical and metaphorical aspects of movement.

Cognitive Approaches

In recent years, research on religion as a means to understand human thought has received a striking new impetus within cognitive approaches to the field. This work has blended the findings of evolutionary and cognitive psychology with those of anthropology. In contrast to the work of anthropologists who emphasize the historical contingency of any given definition of religion, researchers in this subfield have argued that there is a biological basis to religious activity. An important strand has also focused on how counterintuitive or surprising experiences are recalled and transmitted over time (e.g., Boyer, 2001).

Salazar (2010) discerns two main orientations among cognitive researchers. The 'adaptationist' argument states that no human society can survive without language or religion, and so there must be both a language instinct and a religious instinct. The alternative approach is to see religion more as a by-product of evolution. For instance, the so-called Theory of Mind Mechanism can be seen as a cognitive tool enabling humans to interpret a living organism's movements in terms of its inferred intentions: such construal of what is going on in other people's brains is clearly an adaptive skill. As a result of this skill, humans have perhaps also become prone to seeing intention in events, to see them as guided by a controlling force, such as a divinity.

Overall

Both in the past and the present, the ethnographic study of religion has contributed to numerous mainstream analytical concerns, ranging from classic approaches to rationality, symbolism, and social order to more recent studies of transnationalism, materiality, and both cultural and evolutionary change. The study of religion remains in a vibrant state, even as scholars still wrestle with key questions of whether and how religion can be seen as an autonomous area of activity in its own right.

Abstract

Since the idea of religious development merges into the much larger field of the history of religions, this article focuses on religious evolution. Contrary to common belief, it is to the writings of Max Weber that a defensible conception of religious evolution owes the most. According to Weber, Protestantism, though occurring in only one tradition, was, indirectly but crucially, an indispensable precondition for the emergence of modernity cross-culturally, and thus can legitimately be considered an instance of religious evolution. In this comparative studies in the sociology of religion Weber was particularly interested in the emergence of what he called the world religions in the first millennium BC. By calling these new symbolic forms 'rationalized' Weber was pointing to the fact that they were more coherent, more cognitively and ethically universalizing, more potentially self-critical (reflexive), and more disengaged from the existing society than what preceded them. Just as Protestantism emerged out of one of the world religions, so they themselves emerged out of societies organized in terms of kinship and neighborhood in which religion was primarily magical, by which Weber meant, one in which ritual means were used to attain utilitarian ends. This three-stage typology remains fundamental although it can be significantly refined.

Both evolution and development are ways of looking at the history of religion. Development implies some kind of directional change in the history of a particular religion, whereas evolution implies comparable directional changes in a number of religious traditions. Since histories usually describe directional change of some sort, the idea of religious development merges into the much larger field of the history of religions. Therefore this article will focus on religious evolution.

The Term 'Religious Evolution'

The idea of religious evolution, like the idea of social evolution, has been much criticized in the twentieth century, although neither idea has been entirely abandoned. If the notion of religious evolution is to be salvaged it must be dissociated from several preconceptions of its nineteenth century proponents. These preconceptions include the idea that all religions must be fitted into a single (unilineal) pattern, that progression through a fixed series of stages is inevitable, and that more advanced stages are 'higher' (ethically and spiritually better) than earlier ones (Comte, 1830–42; Tylor, 1871; Spencer, 1876–1997; Marett, 1914, etc.). It is the notion of inevitable progress that has been rejected by twentieth century writers; the idea that religious change correlates with social change in comparable ways across traditions can still be defended as 'religious evolution.' Contrary to common belief, it is to the writings of Max Weber (1920–1921, 1921–1922/1978) that a defensible conception of religious evolution owes the most.

The Protestant Ethic

Weber began his study of religion with his famous *The Protestant Ethic and the Spirit of Caplitalism* (1904–05/1930). At first glance, it might seem that this book is simply a developmental history focusing on a dramatic change within a single religious tradition. However, it is clear from the place of the Protestant ethic argument in *Economy and Society* (1921–22/ 1978) and in the *Gesammelte Aufsätze zur Religionssoziologie* (1920–21) that Weber believed that ascetic Protestantism was an indispensable catalyst for the emergence of a new form of society, which he called modern capitalism. Never before the Reformation in the West was the hold of agrarian society, organized through patrimonial (including patrimonial bureaucratic) and feudal political forms, broken through. Once established, however, capitalism became a worldwide phenomenon, even though taking different forms in different civilizational areas. Thus Protestantism, though occurring in only one tradition, played, indirectly but crucially, a developmental role cross culturally, and thus can legitimately be considered an instance of religious evolution.

Since Weber's time there has been a search for functional equivalents of Protestantism in other traditions that prepared some societies better than others and some groups in some societies better than others for the transition to capitalism, or, perhaps better, to modernity (Bellah, 1957; Eisenstadt, 1968). Ernest Gellner made the interesting suggestion that there were elements in all the great traditions, Islam in particular, that might have led to a Protestant-like breakthrough, but that a combination of fortuitous circumstances in Western Europe made it possible for it to occur there (1988). This raises the interesting question of what gave the great religious traditions a rationalizing potentiality even if it was only fully realized in one case.

The Axial Age

In his comparative studies in the sociology of religion (1920–21) and in the sociology of religion section of *Economy and Society* (1921–22/1978) Weber pointed out that in each of the world religions, sometime in the first millennium BC, there emerged prophets or saviors who radically rationalized

previous forms of what he tended to call magical religion. In each case the emergent figure (Confucius, the Buddha, the Hebrew prophets, Socrates, Jesus) preached a systematic form of ethical conduct quite different from the diffuse ritual and sacramental practices that preceded them. By calling these new symbolic forms 'rationalized' Weber was pointing to the fact that they were more coherent, more cognitively and ethically universalizing, more potentially self-critical (reflexive), and more disengaged from the existing society than what preceded them.

Weber's friend, Karl Jaspers, spoke of this period as the Axial Age (1948), and S. N. Eisenstadt has contributed significantly to the further study of what he calls Axial civilizations (1986 and elsewhere). Following Weber one can characterize each of the Axial breakthroughs (first millennium BC China, India, Israel, Greece) as involving, to different degrees and in different ways, an element of world rejection (Weber, 1920/1946). Religious renouncers (Dumont, 1980) in each case called the empirical world into question and, by invoking a transcendental realm, provided a significant degree of tension between worldly interests and religious demands that enhanced the possibility of social change. Although Weber himself contributed to the stereotype of static traditional societies, in his studies of particular traditions he discerned significant possibilities of social transformation (Weber, 1920–1921, 1921–1922/1978).

Subsequent scholars have pointed out the dynamic potentialities in all the great traditions. What scholars such as Gellner have emphasized is that a radically rationalized ethic of conduct, such as that found in Protestantism, was not in itself enough. As long as the existing military, political, and religious hierarchies of agrarian societies could contain these rationalizing potentialities within monastic orders or private conventicles, a new type of society could not emerge. What made Protestantism successful was not just its unique ethic but the possibility of gaining sufficient political influence (in Geneva, the Netherlands, England, and New England) to institutionalize that ethic in the major spheres of social life.

The Shape of Religious Evolution

If Weber had at least two stages of religious evolution, namely an Axial stage correlating with the emergence of historic agrarian societies, and a modern stage for which ascetic Protestantism was an indispensable precondition, did he have any more stages? In looking at his historical sociology as a whole it is clear that he did. The world religions were preceded by societies organized primarily in terms of kinship and neighborhood and in which religion was primarily magical, by which Weber meant, one in which ritual means were used to attain utilitarian ends such as rain, good harvests, human fertility, etc. While such a three-stage typology is for many purposes adequate, it does seem possible to refine it further.

Bellah, in his essay *Religious Evolution* (1964), suggested a further differentiation of the early stages. He distinguished between a 'primitive,' now better, 'tribal', phase, and an archaic phase. Myth and ritual characterize tribal religion – indeed they may be coterminous with hominization itself – but they are myth and ritual of a particular type. The spiritual beings whose activities are narrated in the myths are not gods and are not worshipped. These half-human, half-animal, often ancestral, beings express in archetypal fashion the social and ecological life of the people. Ritual involves the reenactment of the primordial events such that mythical time becomes present, not the worship of distanced deities. Tribal religion is most characteristic of hunter-gatherers, but is also common in horticultural societies. With agriculture and the emergence of complex chiefdoms, and particularly with the early state, archaic religion comes into being. While in tribal societies every clan can be traced to an ancestral being, in archaic societies only the aristocratic lineages claim divine descent. A hierarchic pantheon of gods appears, quite different from the mythical beings of tribal religion. The gods require worship, and, significantly, sacrifice, in many cases human sacrifice, and a differentiated class of priests who supervise the worship. In archaic societies the ruler often claims descent from the highest god, even the claim to be a living god himself. In general, archaic religion is characterized by a fusion of political and religious hierarchy largely missing in tribal society. Examples of archaic societies, often identified as Bronze Age societies, would include third and second millennium BC Mesopotamia, Egypt, the Indus Valley, and North China, but also early first millennium AD Japan, and first millennium AD Meso-America and Peru.

It was in the midst of or on the peripheries of such archaic societies that the axial religions of the first millennium BC emerged. They took the hierarchical tendencies of archaic religion in a radically transcendental direction. All value was seen to reside in a realm beyond this world and thus this world and all the worldly hierarchies within it were relativized and potentially delegitimized. But in most cases the new Axial religions either remained marginal to the centers of power or, if they were recognized by the ruling center, they made compromises with it so that they largely legitimated that center rather than challenged it, thus allowing a quasi-archaic situation to continue. This is not to minimize, however, the importance of Axial religions in the elite education and culture of each of the great traditions. Also, the critical potential of the Axial religions was continually reasserted in the form of heresies, uprisings, and rebellions (Eisenstadt, 1986, 1999), but these were normally either destroyed, marginalized or, if successful, coopted by the existing structures of power.

A simplified way of looking at the shape of religious evolution was proposed by Bellah (1964). He argued that whereas tribal and archaic religions were primarily this-worldly in orientation, which is what Weber, perhaps unwisely, meant by the word magical, the Axial religions were world-rejecting (and thus, for Weber, very importantly, magic rejecting), although they differed as to whether this rejection was to be worked out within the world (ethically), or as far as possible outside the world (mystically). It should be remembered that in its radical consistency Axial religion was never more than the religion of a minority; the majority continued to entertain beliefs and practices continuous with archaic or even tribal religion, which is what Weber meant by the return to the garden of magic (1920–21).

With the Protestant Reformation, however, the belief in a radically transcendent God had dramatic this-worldly

consequences: the consistent demands of an Axial ethic were to characterize every sphere of daily life. But in the subsequent development of modernity, though the this-worldly dimension remained dominant, its transcendental basis became transformed into immanentism, thus returning the modern world in a much different way to this-worldly immanentism of pre-Axial times. Weber clearly observed this transition, but viewed it almost entirely negatively. The modern world of rationalization would run on its own bureaucratic and economic energies without any transcendental sanction, would become an iron cage (1904–05/1930). Charles Taylor has described the same transformation in less somber hues as 'the affirmation of ordinary life' and has stressed growing individuation (1989). In any case, though the world of the Protestant Reformation and the Western world since the eighteenth century (and, more recently, much of the rest of the world, as well) are clearly different, it is doubtful whether the Protestant phase needs to be designated as a separate 'early modern stage' as Bellah did in 1964, or whether it should be seen as merely the opening transition toward modern religion, the contours of which, though it has been developing for several centuries, are still far from clear.

The shape of religious evolution should not obscure its many irregularities, its lack ofunilineal consistency. Regression was always a possibility: Axial Greek civilization did not emerge from the womb of archaic Minoan and Mycenean societies, but only after the breakdown of those societies and the return to tribalism. Stages were sometimes skipped, especially on the peripheries of advanced societies: the Israelite Axial breakthrough began in a tribal confederation on the boundaries of archaic empires; Muhammad grew up in the tribal city of Mecca but founded an Axial civilization, to be sure under Jewish and Christian influence. Not only was every religion from tribal to modern full of internal tensions and divisions but all of them were open to continuous external influence.

The Causes of Religious Evolution

To move beyond description and consider causation is always difficult in historical sociology; nevertheless, how one answers the question of causation, even tentatively, will determine how one understands the entire process. Religious evolution is certainly embedded in social evolution and cannot be understood apart from it. Long-term tendencies, such as the increasing division of labor, the increasing capacity of states to mobilize social power, the development of media such as money and writing, the differentiation of elites of various types as carriers of distinct cultural traditions, the tendency of pre-modern societies to oscillate between political centralization (patrimonialism) and decentralization (feudalism) all influenced and were influenced by religious beliefs and practices.

There has been a tendency among supporters of the idea of social evolution, Marxist and non-Marxist alike, to emphasize economic factors as causal, and religious developments as epiphenomenal. It has been common to believe that Max Weber reversed this understanding and held that religion was primary in social causation. A reading of Weber's entire work, which puts *The Protestant Ethic and the Spirit of Capitalism* in its proper perspective, makes it clear that such was not his belief. Rather, Weber argued for the relative independence of the religious dimension as a factor in social life, but one that always interacts with other factors, notably economic, political, and legal. S. N. Eisenstadt rephrases Weber by showing that it is not just a matter of emphasizing multi-causality: while never sufficient as a casual factor in itself, religion provides the indispensable element of *cultural codes*, not only for the institutionalization of new social forms but, when internalized in personality systems, for new forms of individual motivation as well (Eisenstadt, 1999).

Religious elements have played a critical role in all the great social transitions. Terrence Deacon has even argued that the origin of language among the early hominids was probably facilitated by what he specifically calls ritual (1997). Some primates today can learn words, but only under the most intense pressure of human teaching. Deacon hypothesizes that the bodily and repetitive nature of ritual may have been a necessary precondition for the counterintuitive, from an early primate point of view, shift to symbolic representation that is the basis of language. In any case, Paleolithic evidence, difficult to interpret though it is, suggests that ritual played a central role in creating the social solidarity and respect for the normative order of kinship relations that differentiate humans from other primates.

The transition to archaic society is associated almost everywhere with monumental temple architecture, large-scale sacrifice, and divine kingship. It would seem that the move from the basic egalitarianism of tribal society to the intensely hierarchical and centralized order of archaic societies was only possible with the institutionalization of new religious codes, in association with an unprecedented concentration of social power.

While causal linkages are far from clear, the first millennium BC did see a number of developments that might have prepared the ground for the rise of the Axial religions. These include the beginnings of a market economy, an increase in bureaucratic and military power, and increasing differentiations of social classes, all of which could have given rise to Weber's 'problems of meaning' (1921–1922/1978). But an indispensable precondition for these radical new religious developments was the existence of cultural elites at least to some degree independent of central political power. These include the Hebrew prophets, the Greek philosophers, the Chinese sages, and the Indian ascetics and mystics. It was among these groups that archaic symbol systems were radically reinterpreted in a transcendental ethical and spiritual direction.

The influence of the Protestant Reformation on the emergence of modern society has been the subject of a vast literature. A significant recent development, however, has been the recognition of the importance of a 'disciplinary revolution,' particularly associated with the Calvinist wing of the Reformation (Gorski, 1993). The disciplinary revolution operated at a number of levels: a new code of systematic ethical action expected from believers, new institutions capable of enforcing the code, and new solidary organizations strong enough to influence political and economic developments. The transformation of these new codes under a variety of influences and pressures into such tendencies as utilitarianism, liberalism, Jacobinism, and socialism, and more recently,

individualism and fundamentalism, has significantly affected the shape of and the tensions within modern society.

Thus, viewing the process as a whole, it appears that religious evolution is not only a subject of great interest in itself, but is a critical dimension of social evolution.

Religion, Family, and Kinship

Annette Mahoney, Bowling Green State University, Bowling Green, OH, USA

Abstract

This article examines contemporary research regarding the connection between religious and spiritual beliefs and practices and family structure and functioning. Religion and family are strongly connected, and religious institutions and beliefs influence the formation of families, fertility, childrearing behaviors, divorce, and coping with family conflict. Contemporary research is unfortunately dominated by samples from the US, and more diverse studies are needed.

There are entrenched historical ties between religion and family life across the globe. In the twenty-first century, diverse religious communities on every continent continue to offer their adherents guidance on virtually every aspect of forming and sustaining intimate bonds within family and kinship circles across the life span, including courtship, cohabiting, mating, childbearing, and nurturing family members of every age. Yet, contemporary social scientists have primarily focused on individual religiosity rather than collective commitments when investigating influences between religion and family or kinship networks. That is, most empirical attention is directed toward positive and negative roles that religion can have on individuals' health and psychosocial functioning, rather than on how religion might influence the structure and quality of intimate, close relationships. The relative paucity of rigorous scientific studies on religion within the context of family and kinship relations is illustrated by comparing the number of peer-reviewed studies focused on marriage versus on religion and marriage. When the word 'marriage' is entered as a search term into the three fields of Abstract or Keyword or Subject for the years 1980–2009, the PsycINFO search engine yields 10 322 studies and SocINDEX yields 11 252 articles published in behavioral and social science journals in English. Yet across two reviews that spanned this 30-year period (Mahoney et al., 2001; Mahoney, 2010), Mahoney and colleagues, were able to locate only 131 peer-reviewed studies linking religion and marriage. In this article, I summarize the nature of scientific research conducted on links between these two domains and scientific findings.

To provide a broad perspective on cross-cultural issues that shape peer-reviewed empirical studies on faith and family, the following issues need to be recognized. First, similar to scholarly debates about the ambiguous boundaries surrounding definitions of 'family' and 'kinship,' controversy exists among social scientists about defining 'religion' versus 'spirituality' for the purpose of scientific studies. Clarifying boundaries between religion and spirituality seems pressing given that affiliation rates and public attendance at well-established religious institutions are on the decline in North America, Europe, and Australia. Further, in scientific literature dominated by researchers working in Western societies, 'being religious' is increasingly portrayed as involving membership in a given religious community, adherence to institutional dogma, worship or rituals, and external pressure. By contrast, 'being spiritual' is increasingly framed as a personal connection to what an individual holds as sacred; a private search for enlightenment, purpose, meaning, or virtues and internal motivation. However, organized religion remains the primarily social institution that attempts to promote spirituality, with nearly all Americans who self-describe as 'religious' also describing themselves as 'spiritual.' More pragmatically, academic debates over whether it is religion or spirituality that matters for family relationships turns out to be largely moot in this niche since most studies rely heavily on single-item questions to assess either domain. For example, the vast majority of studies conducted on religion or spirituality and family life from 1980 to 2009 asked if a given household member self-identifies as affiliated with a general religious tradition (e.g., Catholic, Protestant, Muslim, Jewish), attends religious services, or reports that religion or spirituality was personally important to his or her own life. Relatively few studies asked family members about specific religious or spiritual beliefs or practices focused on family relationships that are promoted by diverse religious groups. As a result, it is easy to argue that a global religious variable, such as greater religious attendance, is tied to family functioning for reasons that have little or nothing to do with the content or substance of religious scriptures or teachings, beliefs, practices, or coping strategies that involve supernatural forces. For example, a correlation between higher religious attendance and lower divorce risk can be attributed to social coercion and/or support that spouses receive to remain married because their lives are embedded in a social network that discourages marital dissolution, not because of specific religious beliefs about marriage promoted by religious groups. Social membership in a cohesive secular group that likewise discourages divorce without religious beliefs about marriage could presumably operate similarly to lower divorce rates. Alternatively, the link between greater religious attendance and lower divorce rates could be attributed to the degree to which spouses internalize religious beliefs or behaviors promoted by religious social networks. For example, diverse religions teach that marriages can be imbued with sacred qualities (e.g., everlasting, transcendent) and manifest the actions of a Higher Power. Single-item measures of religious involvement obscure the extent to which secular and religious mechanisms work independently or interactively to foster psychosocial outcomes. However, as highlighted later, some specific religious beliefs and behaviors promoted by some

This article is based on two of the authors' previous exhaustive reviews of the literature on religion, family and kinship: Mahoney 2010; Mahoney, Pargament, Swank, and Tarakeswar, 2001. These peer-reviewed journal articles may be consulted for detailed citations and discussion to support the statements made in the present article.

religious groups have consistently been linked to family structures and processes.

Second, although diverse definitions and compositions of family and kinship circles exist cross-culturally, most empirical studies in the past three to four decades have focused on the role of religion for so-called nuclear family units comprising married, heterosexual couples with children. For example, although numerous small-scale qualitative studies have focused on the role of religion in family life with people with ethnic or religious minority background (e.g., Latter-day Saint, Jewish, Muslim), most of these participants were married heterosexuals with children. Such studies leave many questions open about the relevance of religion for cohabiting, childless or older couples regardless of their sexual orientation, or families with minors headed by single, foster, step, or divorced parents or coparents, grandparents, and same-sex couples. Further, most quantitative surveys of large samples have involved predominantly Christian participants drawn from the United States and have focused on the marital satisfaction of heterosexual couples or their parenting practices. Relatively few large-scale studies have involved people who belong to other types of families and/or non-Christian groups, leaving open much room for rigorous scientific studies on various religious or spiritual beliefs and practices about family life across diverse religious and kinship networks.

Finally, methodological issues constrain inferences that can be drawn from available empirical studies on faith and family life. Namely, most studies rely on cross-sectional rather than longitudinal or experimental designs. This issue makes drawing causal conclusions about the influences between family and religious variables difficult because the relationships may be confounded by other factors such as socioeconomic status, education, and personality variables. Most studies also rely on self-reports from one given family member, rather than multiple family members, for both religious and family variables, and direct observation of family interactions is very rare. These two limitations raise concerns about self-report biases driving associations between religious and family factors.

Relational Spirituality: Organizing What We Know for Family Relationships

Despite the aforementioned challenges in interpreting available empirical research, social scientists have fruitfully examined many family topics in connection with religion. These topics include union formation; maternal fertility; paternal time with offspring; spousal egalitarianism; work–home balance; divorce risk; marital satisfaction; risk of domestic violence and infidelity; pregnancy; discipline, warmth, and physical abuse toward children; parenting style and relational quality with adolescents; and domestic violence and post-divorce adjustment. To organize and clarify consistent findings across this wide range of topics, Mahoney (2010) developed a relational spirituality framework that differentiated three general stages of family relationships: (1) discovery – forming and structuring a particular set of family or kinship relationships, (2) maintenance – sustaining processes in established relationships, and (3) transformation – coping with changes in the structure and/or processes of relationships. This schema has three advantages. First, controversies about religion and family life reflect underlying theological disagreements between socially conservative versus socially progressive religious or secular subgroups over the perceived moral legitimacy of diverse family structures. For instance, within and across religious subcultures, people hold conflicting theological stances about the morality of same-sex marriages, nontraditional gender roles, and the ideal composition of household units. Second, these conflicts between religious subgroups make it easy to lose sight of the fact that many religious subgroups promote similar virtues for how family members should behave toward members of their chosen family and kinship circles (e.g., display love and commitment). Third, it is possible that certain religious beliefs reinforce destructive family processes within subsamples where people are struggling with family-related stressors or dysfunction, yet this also might obscure evidence that religious involvement tends to lower the risk of family-related stressors. For example, although a minority of individuals may draw upon religious beliefs to defend acts of domestic violence or child physical abuse within families where such family problems exist, higher religious attendance generally lowers the risk of exposure to both forms of family aggression based on large heterogeneous samples of people.

Relational Spirituality: Forming Family Relationships

Getting Married

Cross-culturally, adults have historically and continue to rank religious similarity as an important factor when searching for a mate. Men and women express a similar desire for a potential spouse to belong to the same religious tradition (e.g., 'none,' Catholic, Protestant). Couples also decide early in their courtship whether (non)religious compatibility matters. That is, the percentage of couples who have the same religious affiliation does not change across the stages of dating, being sexually intimate, cohabiting, or marrying. Conservative Protestants, Catholics, Latter-day Saints, and Jews are the most likely to marry partners from their religious affiliation compared to others. In addition, those who view religion as more important to their daily life and who more often attend religious services are less likely to cohabit. Similarly, people from all denominations who see religion as highly important more often get married in their early 20s rather than delaying marriage. Higher religious attendance also increases the odds that unmarried, pregnant women will marry after giving birth. Analogously, gay and lesbian individuals who view religion as important more often engage in ritualized commitment ceremonies with same-sex partners.

Maternal Fertility

For centuries, religions have encouraged married couples to procreate. This message continues to sway women. Those who view religion as important to their lives are more likely to give birth after age 24 years. This is consistent with diverse religious teachings that motherhood should be delayed and ideally reserved for marriage. Further, women who report on surveys that religion is unimportant are more likely to have

unplanned births, especially during adolescence, or to remain childless into middle age. Also, regardless of how often they attend services or their particular faith tradition, women's plans to have children are also tied to greater importance of religion in their lives. This finding applies to women who do or do not hold socially conservative attitudes toward feminism or family life emphasized by some religious groups. Overall, adult women who value their religious faith are more likely to have children and want to be mothers. Further efforts are needed, however, to pinpoint specific spiritual beliefs or practices centered on motherhood that motivates this life goal.

Paternal Involvement

Researchers examining married men in the United States have found that conservative Protestant fathers do not spend more time than other fathers with their children. In fact, unmarried American fathers are more likely to avoid offspring born out of wedlock if they are conservative Protestants. On the other hand, across religious denominations, fathers who attend religious services more often are more likely to spend time playing with their biological children. This implies that more intensive religious involvement across the spectrum of religious traditions helps motivate fathers to invest time in creating father–child relationships but more research on this topic is merited.

Home and Work Balance

Couples face complex choices in deciding who does what in and out of the home. Many couples cannot afford for either spouse to be a full-time homemaker, and most heterosexual American wives are employed before and after having children. Thus, couples face a difficult juggling act in assigning the roles of breadwinner and homemaker. Yet Americans from conservative Protestant or Muslim families report diverse values about how couples should negotiate such issues. That is, conservative Protestants and Muslims define equality within families through the lens of their religious beliefs. Contrasting interpretations of the Bible in evangelical Christian circles urge husbands to devote more time to their 'manly' segregated household tasks or to pull more weight across the board. Yet neither message seems to have hit home based on US national data. Conservative Protestant wives do more of both traditional 'female' and 'male' housework than other wives, and conservative Protestant husbands exert the same effort as other husbands on both types of housework. Nevertheless, more progressive Christian couples are not markedly more egalitarian in marital decision making. That is, as a group, conservative Protestant couples are equally likely as other couples to share decisions about financial matters, child-rearing, and who should work outside the home. Thus, although more conservative Christian couples say they believe more in traditional gender roles than mainline/liberal couples, the actions of both groups tell a different story. There is considerable evidence that conservative Protestantism reduces female employment and earnings even more than it does for males, and this reinforces traditional gender investments is careers and family.

Relational Spirituality: Sustaining Family Relationships

Despite theological divisions within and across religious subcultures about whether an ideal family structure is that of married heterosexuals with children, most religious traditions encourage similar virtues (e.g., love, self-sacrifice, commitment) to facilitate the stability and quality of family relationships that do create.

Enhancing Marital Quality

Higher marital satisfaction has been tied repeatedly to each spouse's general religiousness (e.g., religious attendance rates, importance of religion) and husband–wife similarity on such factors. Emerging research offers insights into three specific religious or spiritual constructs that may enhance marital dynamics. First, spouses can view their marriage as having spiritual significance, either by seeing the union as having sacred qualities (e.g., is sacred; is part of a larger spiritual plan) or being a manifestation of God (e.g., God plays a role in; is a reflection of God's will). Several studies show that greater belief in the sanctification of one's union predicts more marital love, satisfaction, and constructive communication processes; such effects are not merely the result of other positive elements of the marriage or spouses' overall religious involvement. Second, couples can engage in intimate discussions about spirituality. Such dyadic activity is tied to higher marital satisfaction and better communication processes. Analogously, college students and mothers who mutually discuss their spiritual journeys tend to have more harmonious relationships and resolve conflict collaboratively. Third, family members can privately pray for the well-being for other family members. Rigorous experimental and longitudinal small-scale studies have found that prayer for a romantic partner or spouse improves relationship quality. In qualitative surveys, married couples report that turning to God as a resource helps them to resolve conflict by encouraging mutual self-reflection, patience, empathy, and accountability. On the other hand, family members may use religious beliefs to escalate distance and conflict between family members. For example, couples who deeply disagree in their interpretation of the Bible experience more conflict.

Decreasing the Risk of Domestic Violence and Sexual Infidelity

According to multiple studies, more frequent attenders of religious services are much less likely than infrequent attenders to perpetrate, or to be the victim of, domestic violence in marital, cohabiting, or dating relationships. Further, conservative Protestant identification, fundamentalist beliefs about the Bible, and interfaith marriage does not increase the risk of domestic violence except when biblically conservative men are married to more liberal wives, which increases the risk of domestic violence.

Individuals who more often attend religious services are also less likely to engage in extramarital sexual relationships. The odds of infidelity paradoxically increase for high attenders who do not feel close to God and for low attenders who do feel close to God. Also, purely private spiritual experiences (e.g., prayer, subjective spiritual growth) make no difference for the likelihood of having an affair. Thus, sexual fidelity seems to depend both on religious

communal support for, and the personal internalization of, a spiritual commitment to sexual fidelity within marriage. Further, sexual infidelity is more likely to trigger a subsequent divorce for couples who frequently attend religious services.

Disciplining and Nurturing Children

Parents with conservative Christian identities (e.g., affiliation, Biblical conservatism) tend to spank children more than other parents. This does not mean, however, that conservative Christian parents are excessively harsh. In fact, in national US surveys, this religious subgroup of parents report yelling less and being more physically affectionate with their children than other parents. Further, in one in-depth study, conservative Protestant parents were no more likely to spank their preschoolers when stressed than other parents and were equally likely to use nonpunitive disciplinary techniques. Further, conservative Protestant fathers report giving their children more affection and supervision than other fathers. Overall, conservative Protestant parents appear, on average, to blend firmness and warmth in child-rearing in a manner consistent with their religious views of parenting. Moreover, some studies have suggested that corporal punishment is less harmful in the normative context of conservative Protestantism.

Much less is known about the ways religion may promote parenting by those who do not identify with conservative Protestantism. Yet higher religious attendance and personal importance of God or spirituality has been repeatedly correlated with positive parenting by unmarried mothers especially at the risk of having difficulties. Namely, these factors predict more satisfaction, self-confidence, authoritativeness, and consistency in parenting as well as less parental distress and risk of child abuse by young, single mothers with limited financial resources and/or from ethnic minority groups within the United States.

Risk of Child Physical Abuse

Multiple peer-reviewed studies show that frequent religious attendance by parents substantially decreases their risk of being physically abusive to their children over time. Further, despite concerns that religiously conservative parents may justify child physical abuse on spiritual grounds, this question has rarely been directly studied. In two related studies, the risk of being abusive toward children was related tied to extrinsic religiousness where people report participating in organized religion for instrumental and utilitarian reasons (e.g., gain status, social support). In contrast, researchers have not found higher rates of child maltreatment to be associated with any particular religious tradition, attendance, orthodoxy, or an intrinsic religious orientation where people report religion is central to their identities and well integrated into their personal values.

Relational Spirituality: Coping with Family Problems

Because more religious individuals more often tend to seek out and enjoy harmonious family relationships, they may be especially ill equipped to handle situations that violate their religious beliefs of how to form and maintain family bonds. However, scarce research exists on the ways people may draw on religion to cope with family problems. Examples of situations where specific religious or spiritual beliefs or practices may impact coping include relying on religion to cope with a romantic partner who will not commit to marriage, coping with a nonmarital birth, dealing with infidelity, responding to domestic violence, or serious dysfunction in marital or parent–child relationships. Such stressful situations may trigger spiritual struggles that contribute to personal and relationship distress. Or, religion may be a well-spring of resilience in times of family trouble. Research on ways people use religion and spirituality to cope with divorce illustrates the potential for religion to help or harm when family difficulties occur.

Coping with Divorce

Americans who often attend religious services and couples who are religiously similar are less likely to divorce in the future than others. Nevertheless, significant percentages of people get divorced, including those affiliated with a religious group. For example, one US survey found that approximately 28% of Catholics, 34% of Protestants, and 33% of 'born again' Christians reported having had a prior divorce. Thus, religion is associated with being less likely to have had a divorce, but many people affiliated with a religion do experience divorce. This raises important questions about religious or spiritual coping strategies and postdivorce adjustment. Initial research on this topic has found that divorcing adults as well as college students with divorced parents often interpret this event as the loss or violation of something sacred and experience spiritual struggles about it. Such religious or spiritual distress exacerbates emotional distress. On the other hand, divorcing adults who more often turn to God and a religious community for support are less depressed over time. The picture is less clear for parental divorce. Young adults who recalled trying to use such spiritual resources at the time of the divorce reported current adjustment. National surveys also show that parental divorce triggers switching of denominations or disengagement from organized religion by offspring. Furthermore, the most highly religiously engaged youth are most likely to experience religious or spiritual struggles and psychological distress over time due to their parents' divorce, whereas those with moderately strong ties to religion who are somewhat engaged in a religious tradition appear more able to draw on religious or spiritual resources and thus may experience less distress over time due to parental divorce.

Relational Spirituality: Deepening Our Understanding of Prevention and Intervention

Overall, scientific evidence to date suggests that religion tends to promote the formation and maintenance of family ties, and thus may help to prevent family difficulties. Yet, much empirical work remains to identify specific resources and struggles promoted by religion that could impact family relationships across diverse types of families and societies, especially for subsamples of people who have become embroiled in stressful family situations. Social scientists could productively build more collaborative relationships with diverse people of faith to conduct more basic and applied research on religious or spiritual beliefs and practices that can help or harm family and

kinship bonds during daily life and times of family crisis. In particular, almost no controlled empirical research exists on the efficacy of incorporating religious or spiritual concepts into established prevention or intervention programs aimed at family issues. Thus, while higher involvement in religion appears to lower the risk of various family difficulties, it is far from clear how to translate such basic research findings into practical applications to help prevent family distress and intervene effectively when family difficulties do occur.

Abstract

This article discusses the way in which scholars, since antiquity, have examined their own and foreign religions and, within this framework, have responded to the pressing cultural and social questions of their day and age. Its aim, therefore, is not to reconstruct the history of religious phenomena as such, but rather the historical developments within the historiography of religion. After an introduction to the latter's terminological history, the article sketches its themes, central concepts, and methods up to the year 2001. This is done as they have emerged from the dialogue between such disciplines as philosophy, theology, philology, history, and ethnology, and with reference to its historically determined cultural, scientific, and institutional contexts. The article closes with a summary of the current trends and perspectives within the historiography of religion, as exemplified by research interests in France, Germany, the UK, and the USA.

Historical Background to the Term 'History of Religion'

The Latin term *historia religionis* first appeared in the sixteenth century and was employed alongside related terms such as *historia ecclesiastica* to entitle chronicles of important events in church history, and the life histories of influential theologians and witnesses of the Christian faith. The term was also applied to accounts on the origin and development of Judaism and portrayals of foreign religions. In his *Historia Religionum* (1697), Gebhard Theodor Meier used the concept in the sense of a comparative study, aimed at portraying a history of the three monotheistic religions. Compared with the more descriptive treatises on religion, comparative *historiae religionis* drew on theological distinctions, such as that between God's chosen people and heathens, to the end of justifying the exclusive truth claims of Christianity. In his *Abris einer Geschichte der Religionspartheyen* (1755), the Protestant theologian and student of Christian Wolff, Sigmund Jacob Baumgarten (1706–57), examined these different methods and aims of religious historiography, explicitly distinguishing between a *usus historicus* and a *usus polemicus*.

From the 1880s onwards we find the introduction of new compound terms of religious historiography which competed with *history of religion*(*s*), *Religions-geschichte* or *histoire des religions* and reflected a heightened interest in scientifically recording and interpreting religious phenomena. The appearance of the terms 'philosophy of religion,' 'science of religion,' 'religious studies,' and – later – 'sociology of religion,' 'psychology of religion,' and 'phenomenology of religion' demonstrated the increasing differentiation within the scholarship dedicated to scientifically interpreting religious culture. However, none of these new academic subjects succeeded in establishing itself as a dominant or authoritative discipline for investigating and interpreting religious systems of belief. Academic research into religion is characterized, rather, by a high plurality of divergent and competitive disciplines that have been institutionalized quite differently, mainly in the countries of Europe and in the USA. This rivalry between disciplines also applies to the historical inquiry into religions: besides professional historians, who sought to render their discipline the new leading human science of the nineteenth century, other cultural scientists and theologians also participated in the historical study of religion and contributed significantly to its advances. As a result, most of the 'classical' works in nineteenth century religious historiography were not compiled by historians but by theologians (or former theologians), philosophers, ethnologists, philologists, sociologists, and professors in the nascent university disciplines, Sinology, Indology, and Egyptology.

In the course of these developments, the term 'history of religion' remained controversial. Friedrich Max Müller (1823–1900), who is regarded as the founder of the 'comparative science of religion' (*vergleichende Religionswissenschaft*), abandoned the term 'history of religion' in favor of the 'science of religion' in order to emphasize the scientific aims of an inquiry directed toward all historically given religious phenomena and traditions, and which strives to emancipate itself from the prejudiced approach of both theology and philosophy. Other researchers of religion, such as Cornelius Petrus Tiele (1830–1902), preferred the term 'comparative religion.' Nevertheless, common to all these different terms and their respective definitions of approach was the motivation to dispense with theologically orientated normative constructions in the study of religion. In Anglo-Saxon countries, this movement found its most important source of support from the so-called 'Lectures,' an institution backed by the private endowments of wealthy patrons (in 1878 Friedrich Max Muller inaugurated the 'Hibbert lectures' and, in 1888, the first 'Gifford lectures' were given). The first professorship for the 'General History of Religion' was established in Geneva, in 1873; in 1877 the universities of Leiden and Amsterdam followed suit. In 1879 France's first chair in *Histoire des religions* was founded at the *Collége deFrance* and in 1886 the Graduate School of Sorbonne, *Ecole Pratique des Hautes Etudes*, instituted its *Section des sciences religieuses*. However, this appearance of several chairs in the 'history of religion' and 'religious studies' did not achieve the full emancipation repeatedly postulated by Christian theologians. In Germany, for instance, most religio-historical chairs were set up within evangelical-theological faculties; and even where this was not the

case and provision made for institutional independence, as in The Netherlands, the majority of scholars appointed to such chairs were theologians.

History of Religious Historiography

The intellectual reflection on religion(s) can be traced back to scholars in Greek and Roman antiquity. Here we find the origination of several important topoi that continue to influence the study of religion (such as the critique of religion, theories on the origin of religion and its social function, the comparison between polytheism and monotheism). Notwithstanding this degree of continuity, the ancient world's approach to the subject of religion cannot be termed 'historical.' Beyond the context of Graeco-Roman traditions, we can also find evidence of the examination of religious life in early Arabic, Persian, and South-East Asian scholarship. However, the influence of these traditions on European historiography of religion has been minimal. One central impetus for broadening Europe's religio-historical horizon was provided by the overseas conquests of the fifteenth and sixteenth centuries. What conquerors and travelers had to report on the foreign religious ideas and practices of the far-off lands they had visited led scholars to question the cultural self-evidence of Christianity, particularly after its confessional pluralization following the Reformation. In an attempt to intellectually overcome religious pluralism as well as the denominational conflicts within Christianity, E. Herbert of Cherbury (1581–1648) focused on a 'natural religion of reason' which he believed to be the true essence of all the different guises of positive religion. In doing so, this British deist introduced a distinction that would later be appropriated by Enlightenment theologians.

However, strictly speaking, it was the seventeenth century that gave birth to the historiography of religion proper. In the wake of the ecclesiastical schism and resultant religious wars, the Christian 'culture of unity' (Troeltsch) began to crumble and was soon replaced by an absolutist state which succeeded in politically neutralizing the vying religious parties by way of an absolute leader ruling over all religious parties. At the same time, the religious conflicts of the seventeenth century gave rise to the interest in a history of religion which was not conceived theologically, but had recourse to an impartial 'third' standpoint beyond confessional polemics. This was found in the 'historico-philological method' based on the principles formulated by Jean Mabillon (1632–1707) in his *De re diplomatica*, which was one of the first comprehensive treatises on methods of documentation and the study of hand-written manuscripts. The publication of this work in 1681 can be seen as the birth of textual criticism that played such a central role in the development of religious historiography. At about the same time, Richard Simon (1638–1712) applied literary-critical methods to the study of the Pentateuch in his *Histoire critique de I'Ancien Testament* (1678) and, in doing so, was one of the first to expose the religious history of the Judaeo-Christian tradition to the process of historicization. This rigorous distinction between the theological and historical historiography of religion also formed the guiding precept of Johann von Gro(e)ing's *Historie der heutigen Religionen* which appeared in Hamburg in 1702. In dismissing every form of *theologia polemica*, this author declared his commitment to a historical approach orientated toward the facts.

That the historian had not irrevocably displaced Christian apologetics, however, is evidenced by Jacques-Bénigne Bossuet's (1627–1704) work *Discours sur l'Histoire universelle* (1681) which appeared in the same year as Mabillon's important treatise and adhered to an interpretation of world history stressing God's saving grace. In opposition to Bossuet, Montesquieu (1689–1755) banished the guiding hand of divine providence from history and declared mankind to be history's focal point. The human being, expounded Montesquieu in *Esprit des lois* (1748), is determined by lots of factors – climate, laws, customs, and traditions as well as religion–the combination of which gives rise to the particular intellectual characteristic of a nation and its underlying 'spirit.' The work of the Göttingen exegete Johann David Michaelis (1717–91) illustrates how Montesquieu's point of departure could be used to widen the religio-historical perspective. According to his own statements, Michaelis sought to view the Old and New Testament 'through the eyes of Montesquieu.' To this end he reconstructed in his six-volume *magnum opus*, *Mosaisches Recht* (1770–75), the structure and contents of the Mosaic codex from the climatic, economical, political, and socio-cultural preconditions of its natural environment, and thereby offered an interpretation of this codex in the spirit of Montesquieu and in reply to the demands of his day.

Alongside this *historico-philological* examination of religion, we also find the appearance of the *psychological* approach to religion, as represented by David Hume (1711–76) in his treatise *The Natural History of Religion*, published in 1757. Hume was not primarily concerned with explaining religion historically, but rather with accounting for religious ideas and practices as phenomena of the human psyche under the dictates of irrational emotions such as fear and hope. Because Hume saw reason as having gradually overcome these irrational forces in the course of history, however, this Scottish philosopher had also furnished the historiography of religion with an evolutionist perspective that would then feature as a key concept in the second half of the nineteenth century.

With the conception of world history as a developmental process from lower to higher, that is to say, from uncivilized to rational forms of life, religion came to represent not an exception to, but a manifestation of these historical dynamics. The evaluation of religion's status within this process of advance was divided: either one adopted a religio-critical stance, and assumed that reason would eventually replace religion (Voltaire, 1694–1778), or one took up a more positive, religio-historical position, and integrated religion into historical progress. One leading exponent of the latter position was Charles de Brosses (1707–77). In his study *Du culte des dieux fétiches* (published in 1760) he employed a comparison between ancient and contemporary African cult ritual to support his claim that fetishism – understood as the worship of arbitrarily chosen natural objects or living creatures – is to be identified as the original form of all religions. However, in the course of mankind's historical advance this has been successively superseded by the worship of celestial bodies, by polytheism, and then finally by monotheistic religions, he contended.

In his *Grundrß der Geschichte aller Religionen* (1787), Christoph Meiners (1747–1810) also construed the history of

religion as part of a general historical process of cultural advance. As a result of this pronounced tendency in the eighteenth century to assimilate the portrayal of religion into an all-encompassing cultural historiography, the traditional anchor of religious history in the theological field of church history began to corrode, causing a telling shift of emphasis. Johann Christoph Gatterer (1727–99), for instance, dealt with church history within the framework of a universal history of religion. In a similar vein, Christian Wilhelm Flügge approached church history as an aspect of religious history that he conceived as a branch of the general cultural history of the human spirit.

Resistance against this linear and optimistic idea of historical progress had already begun to emerge in the eighteenth century. For Jean-Jacques Rousseau (1712–78), scientific and technical progress amounted to a moral step backwards behind the original and good 'natural state.' Even religion, he argued, has not escaped this cultural decline, but degenerated from an honest 'affair of the heart' into an institutionally depraved ecclesiasticism no longer capable of integrating the community. Nonetheless, because Rousseau considered religious feeling to be the strongest social bond, in *Contrat Social* (1762) he spoke up for a religious 'occupation' of the values which hold together the political community, viz. the establishment of a 'civil religion.'

Similar ideas were to be voiced by Alexis de Tocqueville (1805–59) almost a century later who, in his famous work *De la démocratie en Amérique* (1834/40), prognosticated that the a politico-moral consensus within democratic societies would adopt the socially integrative role which religion had played in the social system of the Middle Ages. In eighteenth-century Germany, Johann Gottfried Herder (1744–1803) likewise objected to the belief in progress of Enlightenment thinkers, supporting the Romantic conception of history as a process of organic growth. In doing so, Herder influenced the organo-historical ideas of classical German historicism. This school of thought also rejected the Enlightenment's linear concept of history and belief in universal-historical progress, viewing history as the unfolding of individual cultural units.

The turn of the century into the 1900s was also a transitionary period for European historical consciousness which had begun to move away from universal generality and attach greater importance to that which is particular and individual. This change of perspective not only enhanced the status of the historical religions, which had been neglected by the concepts of historical progress of the eighteenth century, but also paved the way for the empirical research into the history of religion, especially the intensive analysis of ancient religious traditions.

Among others in Germany, Otto Jahn (1813–69) and Karl Otfried Müller (1797–1840) devoted their scholarly activities to investigating ancient mythology. In his influential study *La cité antique* (1864), the French historian N.D. Fustel de Coulanges (1830–89) examined the stabilizing function of religion for the Greek polis and Roman system of rule. Furthermore, this new interest in empirical research into religion led to what Edgar Quinet described in his work *Génie des religions* (1842) as an 'Oriental Renaissance': the first translations of India's holy scriptures had already begun to appear at the end of the eighteenth century.

In 1808, Friedrich Schlegel published his writings on the language and wisdom of India (*Über die Sprache und Weisheit der Inder*) whose conception of religious history diametrically opposed that of the Enlightenment. In India's ancient wisdom, Schlegel saw the realization of a unity between nature and spirit (Geist) which 'enlightened Europe' had forfeited and India itself submerged, and which he strove to reconstruct from the oldest of India's religio-historical sources. Drawing on Schlegel, Georg Friedrich Creuzer (1771–1858) and Joseph Görres (1776–1848) called into question the origins of antiquity's mythical tradition, claiming that Greek myths originally derive from the wisdom of Indian priests. With this Romantic enthusiasm for oriental languages and literature, the availability of translations of the latter and, not least, the advances in the field of 'historical and comparative linguistics since the turn of the nineteenth century,' the historiography of religion in the nineteenth century was afforded a wide range of new stimuli.

The endeavors of Franz Bopp (1791–1867) to distill a common Indo-European proto-language from a grammatical comparison between Sanskrit, Greek, Latin, Persian, and German, for instance, gave the comparative study of religions new impetus, temporarily pushing universal interpretations of history into the background. Aside from the work of Eugene Burnouf (1801–52), a prominent figure in the historiography of Iranian religion, it was above all the services of his, and Bopp's student, Friedrich Max Müller, which rendered the philological approach beneficial to religious historiography.

Analogous to the Romantics' interest in the origins of religious history, Müller linguistically classified the Indo-European languages, particularly with reference to their respective names for God, to the end of reconstructing a primal religion common to all these peoples, which he saw as having once flourished in the advanced civilization of ancient India. Hermann Usener's (1834–1905) investigations into ancient religious history were also based on a combination of philologico-comparative studies and theoretical-explanatory ambitions. With his programmatic work on an interdisciplinary ancient religious history – which his students Eduard Norden (1868–1941) and Ulrich von Wilamowitz-Moellendorff (1848–1931) advanced – Usener not only influenced the study of ancient religion, but also classical philology, art history and oriental studies, not least cultural theory until well into the twentieth century.

Besides the philological exploration of religious traditions, which chiefly focused on antiquity and the Orient, the second half of the nineteenth century also witnessed the proliferation of 'ethnological' research into contemporary, non-European religions which had not been taken into consideration by the romantically inspired religious historiography of such scholars as F.M. Müller. That these religions had become the focal point of attention within nineteenth-century religio-historiographical discourse was due to a revival of the evolutionist theory, aimed at assimilating the individual, historical, and divergent forms of religion into a universally applicable model of cultural advance.

In his major work *Primitive Culture* (1871), Edward Burnett Tylor (1832–1917) held the view that the religions of contemporary tribal societies represented the beginnings of religious history and therefore attached great importance to the investigation of such communities. However, Tylor's claim that animism (the attribution of a living soul to plants, inanimate

objects, and natural phenomena) constituted the primal form of religion was soon superseded by other theories on the origins of religion, the most influential of which was William Robertson Smith's (1846–94) totemism theory tracing religion back to the worship of ancestors symbolized by totemic emblems of plants and animals. Emile Durkheim's (1858–1917) writings on the elementary forms of religious life *(Les formes élémentaires de la vie religieuse*, 1912) can be seen as the most prominent adaptation of Smith's propositions. Religio-historical evolutionism proved to be an extremely resilient paradigm, providing the working hypothesis for James George Frazer's (1854–1941) reconstruction of religious history on the basis of contemporary ethnological material in his famous twelve-volume opus *The Golden Bough* (1890–1915).

In the latter half of the nineteenth century, ethnological and philological investigations into the history of religion found enormous support within academia and aroused ever greater interest among the general public. This trend was evidenced in the UK by the positive response to lectures in this field of study (cf Section Historical Background to the Term 'History of Religion') and the huge popularity of Ernest Renan's (1823–92) *La vie de Jesus* (1863) in France and David Friedrich Strauss' (1808–1974) works *Das Leben Jesus* (1835/36) and *Der alte und der neue Glaube* (1872), as well as Hermann Oldenberg's book *Buddha* (1890), in Germany. *Historical* scientists, by contrast, showed very little interest in religio-historical phenomena; the majority of professional historians adhered to a narrow politico-national approach to their subject in which religio-historical questions remained peripheral.

The few exceptions, held in high esteem today, were then decisive outsiders, such as Jules Michelet (1798–1874), who in his 17 volumes on the history of France *(Histoire de France*, 1833–67) drew attention to the religious folklore of the Middle Ages and, in doing so, became a predecessor of the *histoire des mentalités* (cf Section Overview of Recent Research), or Jacob Burkhardt (1818–97) who in *Weltgeschichtliche Betrachtungen* (1868–73) and *Die Kultur der Renaissance in Italien* reflected on religion as a third historical 'power' (*Potenz*) alongside culture and politics.

The cultural-historical revival at the turn of the twentieth century effectively placed religion at the forefront of scholarly discourse throughout Europe and the USA. The rapid erosion of time-honored cultural traditions, the growing insight into the social costs of capitalist modernization, and the new disintegrative tendencies in many Western societies provoked heated debates on the relationship between the religious history of European countries (as well as that of the USA) and their individual formation processes as modern societies. In defiance of traditional disciplinary borders, the historical research into religion became a central medium for the self-reflection of Western societies. From a systematic perspective, three closely connected issues came to play a decisive role in this intensive exploration of religious history around 1900. These issues included: the participation of religious traditions in the genesis of modern occidental rationalism; the socially integrative potential of religion in functionally differentiated and politically fragmented societies; and the cultural relevance of differences between Christianity's denominations on the one hand, and non-Christian religions, especially those of the East, on the other.

First and foremost, this discourse applied to Protestant theology which had largely viewed itself as a historico-cultural science of Christianity since the mid-eighteenth century and, since the 1880s, became increasingly aware of the interrelations between the Christian religion and its non-Christian environment. Above all, it was the proponents of the so-called 'History-of-Religions School' (*Religionsgeschichtliche Schule*) within German Protestant theology who, in classical exegetic and religio-historical treatises, analyzed the interconnections between Jewish antiquity and the religious worlds of the ancient Orient, and the syncretistic character of Christianity. Although religio-historically minded scholars of the Old and New Testament, such as Hermann Gunkel (1862–1932) and Wilhelm Bousset (1865–1920), as well as the systematic theologian and cultural philosopher Ernst Troeltsch (1865–1923) – named the 'systematist of the History-of-Religions School' – viewed 'religion' as a relatively autonomous cultural power *sui generis*, they nevertheless gave greater priority to investigating the interactions between religious and other spheres of culture. Ernst Troeltsch's 'The Social Teaching of the Christian Churches' (*Die Soziallehren der christlichen Kirchen und Gruppen*, 1912) is regarded as the most important work of this religio-historical group. In this publication, Troeltsch embarked on a cultural-historical reconstruction of the formative influence of Christianity's denominational churches and sects on social ideas and the effects of social structures on the formation of religious ideas and communities. Appropriating the typological distinction between 'church' and 'sects,' developed by his friend Max Weber (1864–1920), Troeltsch differentiated between 'ecclesiasticism,' 'sectarianism,' and 'mysticism' as specific forms of religious socialization. With Weber, Troeltsch shared the ambition to demonstrate the significance of religious ideas and practices for the emergence of the modern world. In *Die Bedeutung des Protestantismus für die Entstehung der modernen Welt* (1906), he focused on Protestantism and Calvinism, in particular.

While Troeltsch transformed church history into the cultural and social history of Christianity, Weber expanded his pioneering study 'The Protestant Ethic and the Spirit of Capitalism' (*Die protestantische Ethik und der Geist des Kapitalismus*, 1904/05) into an extremely elaborate enterprise of categorically comparing the economic ethics of the world religions (*Die Wirtschaftsethik der Weltreligionen*, 1915). In 'The Protestant Ethic,' Weber had inquired into the effects of a religiously shaped *habitus* in areas of life and culture far removed from those commonly associated with religion in the narrower sense of the term – above all, in the economic sphere. In his comparative analyses of the economic ethos of the world religions, however, he primarily concentrated on occidental rationalism and sought to grasp its particularity and formative power on cultural life. Today, scholars are more skeptical of the details of Weber's ideas. Nonetheless, it cannot be denied that the worldwide reception of his theories and derivations in the study of religion has scarcely been matched by any other oeuvre.

Overview of Recent Research

Since the 1960s, the renaissance of religious movements in many societies, the upward trend of 'fundamentalism' and

Protestant sectarianism, the spread of charismatic Christianity, and the manifold processes of a rapidly changing religious landscape (conversions, new syncretism) have attracted the attention of historians and led to a critical revision of the 'secularization theory,' which equated social modernization with a general decline in religion. Religion has been rediscovered as a relatively autonomous system of communication and symbolism which shapes the *habitus* of individuals or identity constructions of social groups, and exerts a positive or negative influence on the development of societies. As a result, the old debates on the definition of religion and master narratives on modernization de-Christianization or secularization are being steadily replaced by micro-studies into the diverse religious milieus of the modern age. While religion has become a central topic in the historical discourse of all countries generally, several national-cultural particularities deserve mention.

In France, the work of Lucien Febvre (1878–1956) and Marc Bloch (1886–1944), together with the journal *Annales, Histoire, Sciences Sociales* (originally entitled *Annales d' histoire économique et sociale)* they founded in 1929, supplied the historiography of religion with an innovative approach which broke with the politico-historiographical tradition of the nineteenth century. Their objective was to uncover a temporal stratum of *longue durée* (Fernand Braudel, 1902–85), that is to say, extensive periods of time which formatively shape not only political and socio-economical history, but also the concrete experiential world of the general population. Concepts stemming from *Annales*-historiography, such as 'structure' and '*longue durée*,' were then applied heuristically to the broader discussion of collective 'mentalities,' from which the historiography of religion profited in particular.

Although the term *histoire des mentalités* soon became a key concept of *Annales*-historiography, no agreement had been reached on the question as to what 'mentality' exactly means. These definitional problems notwithstanding, *histoire des mentalités* can be generally described as an historical discourse directed toward the collective consciousness of an epoch, i.e., its cognitive, ethical, and affective dispositions, which form the unquestioned cultural basis for the daily life of individuals and social groups, thus constituting their identity. In its application to the history of religion, this approach initiated a change in perspective away from the narrow argumentation of ecclesiastical historiography: religious history came to be seen as a history of religious consciousness whose carriers remain for the most part anonymous. Following this, historians of religion in France began to attach less importance to major events, personalities, and institutions, and focus on 'structural-historical' and, in particular, 'anthropological' lines of questioning.

Here their investigations have been concerned with historically varying attitudes to birth and childhood, mortality and death, corporeality and sexuality, nature and the environment, God and the Church, heaven and hell (cf Ph. Ariés, M. Vovelle, J. Le Goff, J. Delumeau). To date, however, exponents of *histoire des mentalités* have scarcely researched the religious culture of more recent history, concentrating rather on the Middle Ages and early Modern Age, and – in co-operation with experts in ancient history such as J.-P. Vernant, M. Detienne and P. Vidal-Naquet since the1970s – on the religious history of antiquity. Further drawbacks of applying this historical approach to religious historiography arise from its emphasis on the alleged durability of mental dispositions, its disregard of the processes of change within religious mentalities, and its neglect of the conflicts caused by differing religious backgrounds (resulting from the acculturation of foreign ideas and practices or due to inner-social differences).

In Germany, the 'socio-historical turn' of the 1960s and 1970s as well as the institutional separation of church history (pursued within theological faculties) and general history encouraged scholars to view religion and confession as nothing other than marginal factors in the history of the modern age. Since the 1970s, however, several attempts have been made to integrate religio-historical perspectives into social historiography (cf W. Schieder, R. van Dülmen, R. von Thadden) and to open up historical research in church history and theology to the methodological debates of cultural and social scientists (cf M. Greschat, K. Nowak, F.W. Graf). Numerous younger historians are now conducting research into a range of religious milieus, such as ecclesiastical organizations and festivities, theological controversies and quarrels over religious symbolism as well as the tense coexistence of Catholics, Protestants, and Jews. The collapse of East Germany, moreover, has generated a new sensibility for the political role of churches and their partly antagonistic, partly affirmative relationship to the 'political religions' of the twentieth century. And last, but by no means least, the holocaust initiated worldwide intensive research into the cultural climate of German Judaism and the conflict-ridden history that finally led to the destruction of the 'German-Jewish synthesis.'

In the UK, discussions continue to be determined by the weight of social anthropology (cf B. Malinowski, A.R. Radcliffe-Brown). Here, from the outset – unlike in Germany – 'society' and 'culture' were seen as one, and consideration given to the class-specific religion of the workforce and the processes of religious change in this country's urban centers (cf H. McLeod). Particularly pioneering were the studies on the connection between religious radicalism and revolution (cf Ch. Hill) and between Methodism and the emerging labor movement (cf E.P. Thomson). Research into the processes of religio-theological differentiation in the Anglican churches has also drawn on the interpretative approach of *histoire des mentalités.*

In the USA, historians of religion since the 1980s have been strongly influenced by the 'interpretative' ethnology (stressing the concept of 'understanding' rather than that of 'explanation') and cultural anthropology of C. Geertz. Beyond the classical self-reflective discourse on the religion of native Americans, the faith of the Pilgrim Fathers, pluralism within Protestant denominationalism, the emergence of a specifically American Catholic self-understanding in the late nineteenth century and a 'civil religion' (N. Bellah) capable of integrating religious pluralism, in the most recent American historiography of religion themes such as gender, race, language, and the religious forms of minority groups have played an important role. In addition, the ethnological debate on 'Writing Culture' (viz. the constructive character inherent in self- portrayal and the description of that which is foreign; cf F. Clifford/G.E. Marcus), the comparative analysis of fundamentalist movements in the

world religions (M.E. Marty), the interpretation of Latin America's religious developments (D. Martin) and the interrelation between law and religion (W. Fallers Sullivan) have featured as central concerns of recent research. Current North American religious historiography has also profited greatly from the application of eco-nomico-theoretical approaches (Stark and Bainbridge, 1985; Stark and Finke, 2000).

Outlook

Religion has gained in importance worldwide and this situation has accordingly afforded the research into religion greater significance. At the forefront of this discourse we find the questions concerning the inter-relatedness of religion and ethos, the political relevance of religion, the construction of religious identities of minority and the conflicts between members of different religions and confessions. The debates on migration, religious conversion and new syncretism have shown, however, that historians of religion find it difficult to precisely grasp the long-term changes of religious mentalities. The correlation of conflict-ridden modernization, on the one hand, and the renaissance of strictly binding religion on the other, promises to become an issue of particular concern in the future: for the rapidly advancing globalization of capitalism, together with its constraints on heterogeneity, will only fuel those religious movements intent on communicating a more fulfilled form of human life which transcends an existence solely defined by the utilitarianism of economic rationality.

Religion: Mobilization and Power

Abstract

Religion has always been a strong force for collective mobilization that influences control of state resources. In earlier eras, religious control over the state was direct, and there was little differentiation between the dominant religious institutions and state power. At the same time, alternative religious expressions and institutions were brutally repressed, and mobilization in favored religious groups made compulsory. The differentiation of religious and political institutions in modern societies has meant that religious groups seek power through the political process, and they are often advantaged by having premobilized resources and a common cultural orientation motivating their pursuit of collective goods. Yet, in diverse societies the collective goods sought by one religious movement often harm members of other religious groups or people who reject religion.

Religion has always been a powerful social institution with the capacity to mobilize resources of societies and use these resources to further particular ends. The way that religion obtains and maintains power – defined as control over collective resources – varies over time and space. Prior to the rise of modern, capitalist nation-states, religion and the state were unified, which provided considerable power for dominant religious traditions and minimal power for minority faiths. In most modern societies, religion has become separate from the state, and religious movements wield power by mobilizing their adherents in the political process.

Religion is a social institution that provides explanations about the supernatural (Sherkat, 2005). The collective nature of religions allows religious institutions to accumulate resources – temples, priests, treasures, and adherents are all physical resources enjoined in religious institutions. Religions also produce potent ideological resources that can legitimate collective action, define collective goods, and motivate the use of social resources (Zald, 2000). Religious ideologies are readily transposed into the political realm, and can justify economic activities and relations of production (Sherkat, 2005). Religious ideological resources are both extensive – they have considerable appeal across time and space – and intensive – they enable control over understandings and behaviors (Young, 2002). Religious schemata are almost always the most powerful ideological elements in any culture, and they help to define collective goods (and collective insults), and direct the propriety of collective action (Snow et al., 1986). Classical treatments often assumed that otherworldly religion would stifle political mobilization; however, contemporary research has shown that religious beliefs, values, and institutions are crucial for supporting contentious tactics (Sherkat, 2005; Zald, 2000; Young, 2002).

Religious Mobilization and Power in Precapitalist States

Before the rise of the modern nation-state, religious institutions were directly involved in the administration of the state and in economic production. Religious institutions were the principal supplier of education and cultural goods (music, art, literature), and they actively funded public works projects, such as roads, bridges, and waterworks. Agents of religious institutions helped codify and adjudicate laws, and they also often served as tax collectors and accountants of public resources (Weber, 1978). Religious institutions from most of the major religious traditions (particularly Christianity, Islam, Hindu, and Buddhism) also controlled large landholdings and were important economic engines for the production of food and other commodities. The overlapping structures of church and state gave religious institutions incredible power in precapitalist societies.

Because of the role of religion in precapitalist societies for the state and economy, religious movements among elites were often sources of political conflict. Religious movements could seek greater power through adjudicating laws in a particular way to favor certain economic or political interests, and they could lobby for alternative taxing arrangements. Yet, radical religious movements that bucked established procedures could run the risk of being branded heretical and squelched. Further, the alignment of religious institutions to existing political and economic arrangements tied the dominant religious groups to the precapitalist political economy (Braudel, 1982). As political economic systems rose and fell, so too did the power of particular religious institutions.

The alignment of dominant religious institutions with political and economic elites often meant that the religious desires of the peasantry were ignored (Stark and Finke, 2000). Peasants were often largely unaware of the supernatural explanations produced by dominant religious institutions, and the masses developed their own folk religions. Sometimes these religious expressions were also violently repressed as heretical movements, as in the frequent witch-burning crusades in Europe, and the repression of Sufism and Mahayana Buddhism in the East (Jensen, 2007). However, often religious minorities were tolerated in precapitalist societies, and many minority religious groups came to fill vital roles in politics and the economy as capitalism developed (Braudel, 1982). This is particularly true for Armenian Christians and Jews in various

societies, Jain and Zoroastrians in India, and Copts in Egypt. As capitalism developed, many of these outsider religious groups gained economic power and pushed for political advantages, and this was particularly effective in Islamic nations where religious strictures prevented Muslims from engaging in finance or brokering business deals that might conflict with Islamic law (Kuran, 2010; Poulson, 2006).

Religion and Social Movements in Modern Societies

The differentiation of political, economic, and religious institutions had a profound impact on how religious institutions engage the state, and how religious groups mobilize resources for their own operations and to impact broader society. The separation of dominant religious organizations from political control of the state and control over the means of economic production secularized political and economic authority (Chaves, 1994); however, this also freed religious institutions from the shackles of political conflict and economic vicissitudes. Disestablishment allows religion to be removed from political and economic problems, and a more diverse set of religious expressions have the opportunity to mobilize as the dominant religious institutions lose the power to repress religious alternatives (Stark and Finke, 2000). Further, developing states have a strong incentive to legitimate their authority using religious institutions (Gill, 1998), perhaps especially when nations are plagued by glaring economic and political inequalities across class and ethnic groups.

The loss of dominant religious groups' political and economic privileges spurred the political mobilization of religious resources. As modern polities began to use the collective resources of the state to produce collective goods like public education, care for the poor and infirmed, adjudicating marriage, divorce, and inheritance, and redistributing lands to the former peasantry, religious movements from the dominant institutions often opposed these efforts (Jurgensmeyer, 2008; Gill, 1998). Religious groups also mobilized to press for the political regulation of free markets for capitalist goods, and religious mobilization has been most animated about regulating the production and sale of proscribed commodities (alcohol, beef, pork, and other drugs), and cultural goods deemed blasphemous or profane (literature, art, music, theater, film) (Sherkat, 2005). Many nations actively tried to reduce the power of feudal religious institutions through anticlerical laws and other proscriptions, such as bans on religious clothing and mandatory secular education. In the nineteenth and early twentieth century such moves were met with resistance by the formerly dominant religious traditions – whether Catholic, Islamic, Buddhist, or Hindu. However, many current controversies over the secularization of the public sphere have mobilized the faithful from minority religious groups, such as sectarian Protestants in the United States, or predominately Muslim immigrant religious groups throughout Europe.

One key focus of religious mobilization has been the regulation of sexuality, particularly women's sexuality. Religious groups from many traditions lobby nation-states to inhibit women's movement, proscribe women from political participation, promote sex segregation in schools and public places, prevent access to contraception and abortion, and criminalize nonmarital sexuality (including premarital, extramarital, and homosexual sex). Religious groups also mobilize resources to ensure that the state promotes their preferred style of dress, usually with the goal of reducing women's sexual expression. Religious movements also lobby modern states to maintain their right to impose forced marriage, and to prevent intermarriage across religious or caste groups. The issue of same sex marriage has created considerable mobilization among religious groups in Western democracies in the last decade, and notably this often pits liberal religious groups and secular movements against varied conservative religious groups who oppose extending marriage rights to same-sex couples (Sherkat et al., 2011). The regulation of sexuality is a prominent feature in religious movements seeking to influence cultural markets like literature, film, and the Internet.

Education is another issue that fosters mobilization of religious resources in the political realm. While feudal societies granted the dominant religious groups control over most educational instruction, advances in science and cultural production gave modern states a stake in making sure that educational attainment was widely available and attentive to scientific and cultural progress. The development of widespread or universal public education presents a clear threat to the hegemony of religious institutions, since scientific discoveries and theories call into question supernatural explanations for the origin and purpose of life, and religious narratives regarding the role of the supernatural in this world (e.g., faith healing, miracles, and explanations for catastrophes). Further, teaching about cultural advances in the humanities and social sciences often grates against the hegemony of religious particularisms, exposing students to alternative values, discourses, and religions, and pointing to flaws and contradictions in traditional beliefs, understandings, and aesthetics (Sherkat, 2005). Religious movements have often been quite successful in co-opting public education, particularly by ensuring that dominant religious traditions are placed into public school curricula, and/or by lobbying the state to support independent religious instruction through religious schools.

Religious movements also have a powerful effect on defining the boundaries of nation-states, and determining citizenship rights. Religious movements throughout the world have been central for motivating political upheavals and revolutions, and have been critical for delineating the geography of states emerging from colonial rule – perhaps the most dramatic example being the division of British colonial control into Pakistan, India, Sri Lanka, and Bangladesh. Within the borders of nations, religious movements often seek to control who is considered a citizen of the state and given privileges of enfranchisement, the right to hold political office or state supported employment, or enjoy collective goods such as education and health care. Religious movements are critical for justifying political exclusion of religious minorities, and this is quite evident in places like Israel, Islamic Iran, and Apartheid South Africa (Dubow, 1992; Sherkat, 2005). Often, religiously motivated political exclusion is furthered by creating restrictive immigration policies that prevent people from alternative religious traditions from entering the nation, and encourage

immigration by coreligionists (as in Israel, Saudi Arabia, and the United States before 1965).

Religious groups also mobilize to maintain their privileged ability to mobilize resources, often by encouraging repression against alternative religious groups (Stark and Finke, 2000; Gill, 1998). Even in many highly secularized nations, state-sponsored religious groups have been granted the privilege of state supported resource acquisition through the collection of religious taxes. Maintaining this requires constant mobilization by religious elites to ensure that the franchise is not lost or divided out to competing religious groups. Even in societies like the United States, where state-sponsored religion ended in the early nineteenth century, religious groups lobby for important advantages like exemptions from taxation for property and religious professionals, discounted mail, and diplomatic support for missions. Notably, in most Western democracies the power of religious movements remains so strong that such privileges are relatively unchallenged in the political process.

The Political Mobilization of Religious Resources

The collapse of feudal and colonial societies placed religious groups at a competitive advantage for mobilizing resources in modern nation-states, and the organizational structure of religious institutions played a strong role in helping religious groups engage the state. Because religion is a collective pursuit, religious institutions enjoyed the benefit of preexisting social networks, as well as the cumulative advantage of premobilized collective resources. In contrast, secular political movements based on social class, regional economic interests, or philosophical orientations would have to recruit members *de novo* and coax them to provide resources for the movement.

Religious groups bring people together for regular ritual interactions, and these interactions take place in defined settings controlled by religious movements and usually staffed and directed by professional religious cadre workers (McCarthy and Zald, 1977). Because all modern religious groups have enjoyed a fairly long period of institutional development, they have accumulated substantial resources, which can be committed to obtaining political advantages. And, the rise of democratic political systems favors religious groups that have access to large numbers of adherents who could be mobilized to co-opt or form political parties, run for political office, and participate in the political process.

At the individual level, religious mobilization is advantaged because social networks among coreligionists provide built-in selective incentives for participating in political movements (McCarthy and Zald, 1977). Most important in these are the sense of solidarity and camaraderie that is fostered in religious groups, which can motivate people to volunteer for political and religious causes. Further, those same networks can enforce norms of participation by ostracizing or otherwise sanctioning free riders. If a political cause is sanctioned by religious institutions, then failing to participate marks one as an infidel and causes a loss of social standing. The importance of religious groups for fostering social incentives for political participation is especially acute in nations with considerable religious diversity and for religious groups with little political power. Powerful religious groups are able to garner resources directly from the state, but minority religious groups or those that lack power must mobilize all of their resources directly from constituents.

The norm of giving time, money, and goods to religious institutions provides a stable stream of resources for religious groups, and these resources accumulate over time, even for religious groups that serve disadvantaged minority groups. The gradual development of segregated African-American Christian denominations in the nineteenth and twentieth century were pivotal for providing resources for political movements seeking civil rights for African-Americans (Morris, 1984). Even for this oppressed minority, regular contributions from individuals gradually led to the establishment of well-funded denominations like the National Baptist Convention and the African Methodist Episcopal Church. Religious groups often become critical indigenous institutions for oppressed populations, and they can provide both tangible and ideological resources to promote political and economic gains for their constituents (Billings, 1990).

Religious organizations have control over valuable physical resources, including buildings, schools, temples, printing presses, cars and buses, and communication equipment, such as radio and television studios. Religious schools and temples provide control over space where congregants and leaders can mobilize for political action, plan strategies for action, and retreat from repression. Schools and temples also serve as centers for communicating religious narratives, and these are often fused with the framing of political issues (Poulson, 2006; Morris, 1984). Schools for religious professionals are also critical for mass mobilization potential. First, seminaries for religious professionals are less likely to come under the control of the state, and it is a direct assault on a religious group if a political movement seeks to take over religious schools. Second, seminaries promote social network ties among religious professionals, and they forge a web of like-minded ministers who could be called upon to deliver congregational resources in the future. Third, schools for religious professionals are distinctive in that they train individuals to become leaders of organizations where the mobilization of resources is crucial for day-to-day functioning. Priests, ministers, imams, and gurus are professional social movement cadre workers, and since religious movements have political interests these professional activists are ready-made leaders for political movements.

Religious Ideologies and the Framing of Political Issues

Religious ideological resources are a definitive source of power for religious institutions, and religious understanding help shape the framing of political issues. Religious narratives allow social movements to define problems in sacred terms, and to link solutions and potential outcomes to prophetic narratives that resonate with potential constituents. Religious framing also helps social movements to couch the opposition in an unfavorable light, and to justify extreme tactics against the state or other social movements (Jurgensmeyer, 2008). Because religious narratives are widely understood and often strongly

held (Young, 2002), they serve as a useful tool for mobilizing adherents and for legitimating policy.

Sacred texts from all religious traditions contain narratives that explain how human societies operate in the real world. Often such narratives explain the causes of human suffering, and propose supernatural solutions, which also often have material consequence. Because religious narratives are fluid and can be interpreted through the lens of distinctive faith commitments, the transposition of religious schemata into the political realm is often contest. Indeed, some of the most serious religiously motivated political conflicts arise within religious traditions (Sunni vs Shi'ite in Islam, and Catholic vs Protestant in Christianity). Narratives of suffering and subjugation are juxtaposed with theodicies of release and redemption, and these are commonly used to motivate mobilization.

For example, in the Abrahamic tradition, the story of bondage in Egypt is resolved through the Passover narrative where an angel kills Egyptian children, and Moses leads the faithful out of Egypt after Pharaoh's army is destroyed by God. Such narratives provide political movements with a divinely inspired hope for emancipation, and provide divine sanction for genocidal treatment against opponents. The messianic prophesies of many religious traditions lend a similar justification for establishing theocratic rule and fulfilling the revelations (Jurgensmeyer, 2008). Other narratives point more explicitly to longstanding inter- or intrareligious conflict, such as the veneration of the martyrdom of Hussein in Shi'ite Islam, which provides a resonant narrative to their claim to legitimate rule and the illegitimacy of the Sunni Caliphate (Poulson, 2006). Religious framings help to amplify beliefs about the seriousness of political issues, the identification of unsavory targets for blame, and also about the propriety of mobilizing for political action (Snow et al., 1986). The issue of the propriety of collective action often requires theological innovation for otherworldly religious traditions, since mobilizing for political gain in this world runs contrary to religious emphases on otherworldly salvation (Morris, 1984; Sherkat, 2005).

Current Trajectories of Religious Mobilization and Power

Classical theories of secularization predicted that religious disestablishment would lead to a decline in the importance and power of religious institutions; however, the formal disconnection of religion from politics and economics instead has made religion a key player, particularly in developing democracies and postcolonial societies. Even in highly secularized nations where religion had lost power, immigrant religious groups, particularly Muslim immigrants, have mobilized to garner additional rights like religious schools and legal systems, and to confront threats against religious particularisms, such as antiveiling laws and building codes that prevent the construction of mosques (Just et al., 2014). Indeed, after the fall of the Soviet Union there was a flourishing of religious mobilization among Orthodox Christians and Muslims (Froese, 2008), and religiously inspired political movements have given considerable power to religious groups throughout the former Soviet Union. The rise of a politically powerful Russian Orthodox Church and political Islam in many former Soviet Republics has resulted in the harsh repression of minority religious movements and secular movements. Similar religiously inspired regimes have come to power in many nations throughout the world and across a variety of religious traditions, Buddhism in Southeast Asia, Hinduism in India, Islam in much of Africa and Asia, and Christians in parts of Africa and North America (Jurgensmeyer, 2008). Powerful religious movements from disparate traditions continue to foment devastating violent conflicts throughout Africa, the Middle East, and Southeast Asia.

The political mobilization of religion remains substantial, and the power of these movements to impact social life is considerable in most parts of the world. Further, in a globalized society, religiously inspired political movements and conflicts spillover into international politics and affect the operation of the global economy – almost always in a negative way (Beyer, 1994). Religious institutions have become increasingly international or global in scope, and this has given rise to politicized movements that operate worldwide, particularly in Christianity and Islam.

Abstract

Religion, morality, and social control have been inexorably linked for centuries. In fact, some argue that morality and social control are derived fundamentally from religion. Dominant religious bodies in many societies define correct behavior, codify conduct, and establish social control systems designed to enforce systems of behaviors. This article begins with a discussion of morality, including its definition in the social sciences and how it both influences and is influenced by society. Social control is treated similarly, with attention to different types of control, distinct types of social control organizations, whether social control is unduly influenced by elite members of society, and whether its differential impact on people is distinguished by class, race/ethnicity, and gender. The role of religion in defining and being affected by morality and social control is presented next. This section addresses how various aspects of religion affect moral behaviors and serve as social control mechanisms. The final section discusses how religion is sometimes cast as immoral and deviant.

Religion, morality, and social control have been inexorably linked for centuries. Sacred mandates such as the biblical Ten Commandments, the *pañcasila* (five precepts) of Buddhism, and the Nine Beliefs of Hinduism were used – and are still used – to guide appropriate conduct and organize proper societies. Each includes moral guidelines that adherents are expected to observe. Moreover, the broader literature in which they are found outline systems of social control that are designed to discourage adherents from stepping outside moral boundaries (e.g., Deut. 22:24; Qu'ran 5:38).

In fact, some have argued that morality and social control are derived fundamentally from religion. Dominant religious bodies in many societies define correct behavior, codify conduct, and establish social control systems designed to enforce systems of behaviors. This may occur even if government sanctioned social control mechanisms do not consider a behavior as improper. Moreover, although the direct influence of religious organizations on social life has waned in most modern societies, remnants of their moral guidelines and control functions remain.

There is a persistent unease in the social sciences, however, with how morality and social control are defined and what these definitions imply for our understanding of religion, social structure, culture, and myriad other social phenomena. It is therefore important to review historical and contemporary understandings of morality and social control before addressing their associations with religion.

Morality

Several of the founders of the social and behavioral sciences had a keen interest in morality. It may be said that this interest was fundamental since one of the founders of sociology, Émile Dürkheim (1973 [1925]), sought to establish a discipline by focusing on how morality was a reflection of the nature and organization of a society. Sigmund Freud (1989 [1930]) discussed how ignoble human desires, if left unchecked, would lead to annihilation, so laws guiding moral sensibilities – fostered early in life – were needed to quell this tendency. Bronislaw Malinowski (1926), based on his fieldwork among the Trobriand Islanders, argued that life among so-called savages was not anarchic; rather, their lives were guided by moral rules that imparted practical guidance and served to bind them together in a community. Unfortunately, the examination of the origins of morality lapsed as a topic of interest for several decades.

There has been a resurgence of academic interest in morality in recent years, especially in sociology and psychology (Black, 2011; Haidt, 2007; Hitlin and Vaisey, 2010). This revivification has focused on (1) defining morality more precisely; (2) identifying the sources of morality at the micro and macrolevels; and (3) understanding the cultural implications of moral meanings and judgments (Hitlin and Vaisey, 2010). In its simplest form, morality involves 'rules of conduct' or what have commonly been called 'norms' (Black, 2011, p. 11). Yet, this term has also been distinguished by an emphasis on (1) behaviors that are deemed right or wrong, good or bad, or acceptable or unacceptable; or (2) as a way to judge the appropriateness of certain behaviors. Some suggest that these are interdependent since judgments of appropriateness – if they are truly 'moral' – must occur in some general sense and not be based simply on individual preferences or wishes (Smith, 2003). The evaluation of moral actions is therefore built on general rules of conduct (which include a sense of duty or obligation) that are shared by some set of people and apply in particular situations. Thus, it is contingent since moral actions and judgments often depend on contextual factors, for example, what is appropriate conduct at home may not be appropriate at school or in the workplace.

Observers have also argued that the sources of morality may be found at both the micro and the macrolevels of analysis. At the microlevel, individuals are not atomistic, making choices unfettered by others. Instead, they are part of a hierarchy of individuals and groups that define what is desirable and the accepted means to achieve it. The common sociological and psychological concern with 'socialization' illustrates how important others are in inculcating a sense of what is moral. At the macrolevel, differential group resources and authority serve

to establish what is acceptable and unacceptable. Some conflict theorists contend that powerful groups disproportionately define morality in most societies. Social movement theorists suggest that shared interests among group members galvanize definitions of acceptable vs unacceptable actions. However, many social movements are animated by a shared sense of morality that precedes group formation.

Morality is also influenced by culture and gives rise to worldviews and meaning structures that result in self-identification and salience. 'Moral meanings' affect (1) group solidarity; (2) judgments and even condemnation of outsiders; and (3) narratives designed to explain one's life and identity (Haidt, 2007; Hitlin and Vaisey, 2010). These narratives and associated worldviews support group formation and are encouraged by group membership. For example, conservative and liberal worldviews are centered on different models of moral meanings (Lakoff, 2002). When generalized moral judgments are classified into five domains (harm/care, fairness/reciprocity, in-group/loyalty, authority/respect, and purity/sanctity), liberals tend to endorse harm/care and fairness/reciprocity. Yet conservatives tend to weigh each of these equally. This attention to how morality is cognitively organized and used helps explain the many recalcitrant political, social, and economic disputes in the United States (Graham et al., 2009).

Social Control

The term social control has had a similar conceptual life course as the term morality. Early definitions focused on premodern groups and held that social control consisted of shared norms and practices designed to penalize deviants (Horwitz, 1990). A more general definition expressed that social control entails social relationships, processes, and intentional actions that sustain social conformity, thus regulating deviant behavior (Liska, 1992). This includes relationships, processes, and actions that take place in families, the workplace, schools, and religious and legal institutions (from police to prisons). Moreover, it may include any number of actions, including mild verbal correction, humiliation, ostracism, banishment, fines, beatings, incarceration, and execution.

Attention to this concept intensified during the early decades of the twentieth century as sociologists attempted to study what was happening to social relationships as large numbers of people moved from rural areas and small towns to urban areas. Social scientists investigated whether the primary relationships, processes, and actions that sustained conformity in small towns were transferable to – or as effective in – urban areas where social relationships tended to be more fleeting and not as intimate (Meier, 1982). Subsequently, researchers tended to address other topics, such as (1) different types of control, such as external vs internal or formal vs informal; (2) distinct forms of social control organizations; (3) whether social control was disproportionately established and unduly influenced by elite members of society; and (4) the differential impact of social control agencies on people distinguished by class, race/ethnicity, and gender.

The emphasis on external vs internal and formal vs informal control led to numerous studies of adolescent and adult deviance, in particular criminal behaviors, sexual deviance (a rapidly changing concept), self-destructive behaviors, and mental health problems. Some scholars distinguished between internal forces, such as personal beliefs and values, and external forces, such as parental discipline. A recent type of internal control that has gained significant attention in studies of crime and delinquency involves self-control. Individuals lacking self-control tend to be "impulsive, insensitive, physical (as opposed to mental), risk taking, [and] shortsighted" (Gottfredson and Hirschi, 1990: 90). Its advocates maintain that a parsimonious explanation of deviant behavior is low self-control, which heightens the risk of inappropriate conduct when opportunities are present. Whereas this is a highly individualistic form of internal control, others have examined informal and external mechanisms of control by family members, teachers, and peer groups, and formal mechanisms of control by the police, the courts, or the mental health system.

Conflict theorists were instrumental in drawing attention to how elite segments of society influenced the development and execution of social control mechanisms. They also argued that social control processes disproportionately affect less powerful segments of society (Liska, 1997). Studies demonstrating a positive association between the concentration of poverty or the percent of ethnic minorities and police arrest rates have illustrated that low status groups, as well as low status communities, tend to be unduly targeted – explicitly or implicitly – by systems of social control (Eitle and Monahan, 2009). Similarly, neighborhoods with a high concentration of minority groups or a high degree of poverty are often labeled as areas in need of social control, even after taking into account rates of actual deviance in these neighborhoods (Sampson and Raudenbush, 2004). However, others have pointed out that social movements, which may or may not represent elite interests, are particularly instrumental in influencing social control (e.g., prohibition). Moreover, a key hypothesis that emerged a couple of decades ago focuses on how perceived social threats from deviant behaviors or even from groups seen as involved in these behaviors lead to an escalation in social control efforts, such as more arrests, mental health admissions, and curfew laws (King and Wheelock, 2007; Liska, 1997).

How is Religion Related to Morality and Social Control?

Although the previous sections were presented independently, it should be clear that morality and social control are inexorably connected. After all, the main focus of social control – deviance – is based on judgments and viewpoints about morality. Moreover, any maintenance of morality must be structured by some type of social control mechanism, whether it involves familial or community rules of conduct, or state-run organizations designed to enforce laws and regulations.

In fact, Dürkheim's early work posited that conformity resulted from external sanctions, whereas his later work emphasized that moral behavior was guided by internalized rules or controls. These could be so powerful that they inhibited even the calculation of deviant behavior

(see Wikström (2006) for a contemporary version of this argument). Yet, the distinction between morality and social control is not clear in these works. Are moral meanings or viewpoints simply a type of internal social control? Present-day scholars studying morality and social control have tended to distinguish the two, with moral meanings making control either more effective or unnecessary (Wikström, 2006).

Nevertheless, Dürkheim, Freud, and others did address the role that religion played in the development of morality and social control. This concern led to different conclusions, with Dürkheim seeing some forms of religion as offering sources of common moral standards, thus enhancing the integrative functions of a society; and Freud outlining some harmful aspects of religiosity and its influences on social control.

Contemporary research on religion, morality, and social control addresses (1) the sources of moral beliefs and meanings in religion; (2) the effects of religious beliefs and practices – and how these may serve as social control mechanisms – on moral beliefs, attitudes, and behaviors; and (3) the contingent and macrolevel influences of religion on moral behaviors.

It is evident that throughout history moral beliefs and meanings have been found in religious teachings and practices. Sacred texts are replete with instructions on what is permissible or encouraged and what is prohibited or discouraged. As noted earlier, many of the sacred texts of the world's major religions, such as the Torah, the Old and New Testaments, the Qu'ran, the Vedas, and many of the sayings attributed to the Buddha, describe specific prohibitions, and some outline the risks inherent in particular behaviors (e.g., eternal torment, stoning, banishment). Several of the prohibitions and sanctions taught by these religious traditions are still in force, even though, in quite a few nations, the behaviors they seek to influence are no longer forbidden under formal systems of social control (e.g., adultery, premarital sex, homosexuality).

Nevertheless, it is important to acknowledge that moral beliefs and meanings are not consistently derived from religious institutions or teachings; they may be spring from various other sources, including rational evaluations of one's own and others' actions, altruistic and empathetic tendencies, and even enlightened self-interest (Baggini, 2003). Moreover, contemporary studies suggest that general moral rules are less influential in predicting behaviors than are immediate concerns, emotions, and heuristic tools. Thus, we find that people naturally search for a moral explanation following some behavior, even if it is not generally considered moral by one's peers (Bloom, 2012; Haidt, 2007). This may help explain why religious beliefs and practices are not consistently associated with moral acts. Consider that the Inquisition and the institution of slavery, as well as Mother Teresa's work with lepers in India and Martin Luther King's calls for racial equality and justice, had religious underpinnings.

A vast number of studies have examined the effects of religious affiliation, beliefs, and behaviors on attitudes toward moral issues and the performance of moral and immoral behaviors (the definition of morality used in these studies is not consistent, however). In other words, religion as a form of social control – a topic with a long history of academic interest (Ross, 1896) – has become focused on how particular aspects of religiosity affect individual-level attitudes and behaviors. Empirical research suggests that belonging to a conservative Christian denomination, believing in the inerrancy of the Bible, seeing God as a father figure or a severe disciplinarian, and participating more often in religious services are associated with stricter or more traditional views about abortion, pornography, same-sex relations, corporal punishment, capital punishment, euthanasia, and several other social, political, and cultural issues (Greeley and Hout, 2006).

The association between these religious characteristics and actual behaviors is less certain. One consistent finding of this research involves sexual behavior among young people: those who are highly religious tend to delay sexual initiation, have fewer sexual partners, and are more likely to be monogamous; even though they are, in general, as likely to engage in sex as other youths (Bader and Finke, 2010; Regnerus, 2007). Similarly, most studies have found that stronger religious salience and greater participation are negatively associated with illegal drug use (e.g., Bahr and Hoffmann, 2008). Less consistent, though, is the association between religion and criminal or delinquent behavior, suicidal tendencies, and mental health problems. Early studies found weak to no associations between aspects of religiosity and these outcomes. Subsequent research has found stronger evidence of associations, but they tend to be contingent on other factors (Hoffmann and Bahr, 2005).

The most common finding of recent studies is that participating in a religious community, such as by attending worship services, volunteering for a religious organization, or being part of religious youth and adult groups, is negatively associated with engaging in deviant behaviors. The effect of religious beliefs is substantially weaker, however. Thus, some observers claim that it is enmeshment in religious social networks and a community of religious adherents that serves as a social control against what members see as immoral activities (Graham and Haidt, 2010). It also encourages moral behaviors, such as altruism, charitable giving, and perhaps even healthy physical activities (Bloom, 2012; Hill et al., 2003).

Another important finding involves macrolevel religious influences. This has been approached in two ways. First, the moral communities' hypothesis contends that individual-level religion exerts the strongest negative influence on deviant behaviors, especially delinquent behaviors, in communities relatively high in religiosity (Stark and Bainbridge, 1997). Presumably, when communities are high in religiosity, this reinforces the religiosity of the individual and thus behaviors are affected more.

Second, several recent studies examine whether macrolevel religious influences positively affect aggregate levels of moral behaviors, or have a direct impact on individual-level moral behaviors. For example, cities with higher rates of church attendance tend to have lower crime and suicide rates (Stark and Bainbridge, 1997). Areas that have a higher degree of religious homogeneity (the extent to which residents are members of a single or a smaller number of religious faiths) have lower rates of suicide, divorce, and violent crime, and more religious areas produce a lower risk of

suicide and suicide attempts (Ellison et al., 1997; Trawick and Housen, 2006; Lee and Bartkowski, 2004; Maimon and Kuhl, 2008).

It appears, therefore, that religious adherence and participation at the aggregate level serves as a form of social control – or social integration mechanism – that reduces the risk of some forms of deviant behavior. Presumably, this reflects some enhanced level of morality tied to religion, at least in the United States (although there is also evidence of this in Muslim nations; Huang, 1996), yet it is not the direct function of religious beliefs per se. In other words, religious beliefs, although they typically indicate some generalized support for morality, do not translate directly into moral behaviors. Instead, it is enmeshment in moral communities – aggregates of religiously involved people – that enhance generally accepted moral behaviors and diminish deviant behaviors.

Religion as Immorality and Deviance

A disparate thread of social scientific attention is to religion as deviance and immorality. Moral crusades have been undertaken countless times against religious groups. The Crusades, the many periods of persecution of Jews, religious conflicts between Catholics and Protestants in sixteenth- and seventeenth-century Europe, the execution of hundreds of Christians in seventeenth-century Japan, the Mormon expulsion from Missouri and Illinois in the 1840s, the Branch Davidian conflagration, the massacre of Muslims in Kosovo, and the continuing conflicts between Muslim Pakistan and Hindu India are but a few examples of how perceptions of outsider religious groups can turn to violence. Although persecution, mass executions, and ethnic cleansing are extreme forms of social control used against religious groups, many more subtle methods have also been used.

The pejorative use of the term cult brings to mind how some religious groups are seen as deviant and often labeled as immoral due to their beliefs and behaviors. Yet virtually all major religious traditions began as deviant groups, at odds with the prevailing culture and acting in a manner that was easily termed abnormal or illicit. For example, the early Christian church was illegal during certain periods of the Roman occupation and persecution – by Romans, Jews, and others – for perceived immoral practices was rampant. Not only were they considered deviant for not worshipping Roman gods and for failing to require converts to be circumcised, but they also were the object of rumors of child sacrifice and cannibalism (Gaddis, 2005).

Moreover, religiousness has often been linked to mental illness. Whereas many early psychological and psychiatric researchers assumed that religious believers were likely delusional or prone to mental illness (and thus labeled as deviant by the prevailing medical standards of the time), more recent scholarship has disproved this assumption. Most studies find that those who are enmeshed in a faith tradition are less likely to experience a diagnosable mental disorder, and that they report higher levels of life satisfaction and happiness than others (Ellison, 1991; Koenig et al., 2012; Stark and Bainbridge, 1997). Once again, this may reflect the beneficial aspects of belonging to a community of like-minded people who provide social support and sustenance, rather than a unique effect of religious participation or beliefs.

Religion: Nationalism and Identity

John Myhill, University of Haifa, Haifa, Israel

© 2015 Elsevier Ltd. All rights reserved.

Abstract

In the last decade, it has come to be generally recognized in Western countries that religious identity has not been eclipsed by national identity but remains as a powerful political force, interacting with national identity in complex ways and sometimes superseding it. Much of the most obvious evidence for this comes from an increased awareness of and contact with Islam, particularly because so many Muslims believe that loyalty to the Muslim *'umma*, i.e. the community of all Muslims, is more important than loyalty to the nation or state. This is reflected in the behavior of Muslim immigrants to Western countries, the powerful effect of religion on democratic elections in Muslim countries, and violent conflicts between Muslims belonging to different sects but having the same nationality. But similar interaction can also be found in non-Muslim societies. Religiously-motivated Christians, Hindus, and Jews in Western countries, India, and Israel have become increasingly sophisticated in terms of using democratic institutions to influence national policy and decision marking in accordance with their own religious convictions.

The understanding of the relationship between religion and nationalism has changed dramatically in the last decade or two. Prior to this, the modern understanding had been that religion and nationalism, and religious and national identity, were naturally opposed in the sense that to the extent that states and individuals emphasized one, they deemphasized the other, and that furthermore there is a general evolutionary trend in human societies toward national allegiance at the expense of religious allegiance. But toward the end of the last century, an increasing amount of research began to suggest that this was not necessarily the case, and scholars began to reevaluate and rethink the relationship between religion and nationalism. Today the tide has turned entirely, in terms of both intellectual developments and real-world events, and the question is not whether religion and nationalism are in conflict or not but rather what the nature of the relationship between them is and how it can vary from case to case. Scholars no longer ask whether religious allegiance is politically relevant in the modern world, but rather how it is politically relevant. So in the last decade it has become increasingly mainstream to discuss theories of the relationship between religion and nationalism (e.g., Bader, 2007; Brubaker, 2013; Buruma, 2010; Casanova, 2009; Gorski and Altinordu, 2008; Martin, 2005; Turner, 2011) and cases of interaction between religion and nationalism in constructing political identities in the past (e.g., English, Dutch, and Swedish nationalism in Ihalainen (2005); Polish nationalism in Zubrzycki (2006); Slovenian nationalism in Mihelj (2007); Sinhalese nationalism in DeVotta (2007); Japanese nationalism in Fukase-Indergaard and Indergaard (2008); Finnish nationalism in Tilli (2009); etc.). This is no longer seen as revolutionary or even controversial.

For these reasons, the present article will focus on recent events that show something about the relationship between religion and nationalism in the present day, which should give some idea of what we might expect in the foreseeable future. Most of the events which will be discussed here have taken place in the last decade, although a few took place a bit earlier. In terms of recent events, it has certainly been the connection between Islam and nationalism that has brought the most attention to the question of the relationship between religion and nationalism in the modern world, and so this will be the first topic to be addressed here. This has taken several interrelated forms.

First, in the second half of the twentieth century, as a result of the catastrophe of the two world wars and the end of the age of colonialism, nationalism and racism were ideologically discredited, and this, combined with the apparent success of the American melting pot experiment, led Western European and Scandinavian countries to adopt immigration policies allowing people of diverse ethnic backgrounds to move to, live in, and in many cases become citizens of their countries. The assumption was that in the modern world national identity in the form of citizenship would trump other factors – ethnicity, race, and religion – so that even when a state has taken what was proclaimed to be a multicultural approach to immigration, the implicit or explicit understanding was that it would be the immigrants who would accommodate the state that they have chosen to become citizens of, not the other way around. But in the last few decades it has become apparent that things are not necessarily so simple, and while complications in this regard have been perceived with a number of immigrant groups, there is no question that Muslims have been understood to be the most generally problematic in this regard, particularly in terms of publicly expressing the expectation that they will be able to live under Islamic law in Western countries, and in some prominent cases even carrying out violent and sometimes fatal politically motivated attacks against non-Muslim citizens of the countries they live in. In terms of the issues of identity which this review focuses on, there is a perception (right or wrong) that for many Muslims, contrary to the assumptions that lay behind post-World War II immigration policies, religious identity as a member of the worldwide Muslim *'umma* is more important than citizenship in the state they have immigrated to, so that they assume that it is the state that must accommodate to Islam and not the other way around. This has resulted in a prominent public dialogue on issues related to immigration, multiculturalism, and cultural accommodation, couched, in principle, in general terms but tending to focus on the place of Muslims in Western societies in particular (see for example Bawer, 2006; Bruckner, 2007; Buruma, 2006; Caldwell, 2009; Lentin and Titley, 2011; Saunders, 2012; Triandafyllidou et al., 2011).

Second, there has been a recognition, particularly in the last decade, that the understanding of the *'umma* in the Muslim world is generally a challenge to the assumption that citizenship-based national identity must trump religious identity in the modern world, not only in terms of how Muslims relate to Western states but also in terms of what happens in countries in which Muslims are demographically and politically dominant. The *'umma* can be perceived as either being transnational, with loyalty to Islam transcending loyalty to the nationality, or alternatively itself constituting a nationality of a type radically different from that found today in Western societies, but in either case, understanding it – let alone dealing with it – requires some sort of rethinking of the traditional Western modernist conceptualization of the relationship between religion and nationalism (see e.g., Jones and Mas, 2011; Mandaville, 2011; Saunders, 2008; Zubaida, 2004).

Third, the general assumption of modern Western society has been that the establishment and spread of democratic institutions must be associated with secularization, so that, in the terms of this review, the right to participate in democratic elections motivates people to identify more with their national identity as citizens of the country whose leadership they have actively participated in choosing and less with their own religious affiliation. Until relatively recently, countries in which Muslims are politically dominant did not provide evidence to the contrary, because they generally had not developed democratic institutions. It thus seemed natural to assume that they would go through the same evolutionary process when they developed such institutions. But since the end of the Cold War, which gave a big push to the general spread of democratic institutions to countries all around the world, and increasingly in the last decade, it has become apparent that things do not necessarily work this way in Muslim countries – in many cases, it seems that it is particularly when Muslim citizens are allowed to vote and their votes mean something that their countries become more overtly Islamic. The most prominent example of this is Turkey, where it is clear in retrospect that it was only repeated coups by the avowedly secular military against democratically elected governments that were perceived as too Islamic, that made it possible to maintain the façade of a country that was Muslim, democratic, and secular – in the last decade. As the military has been effectively eliminated as a political force and the Turkish people have been free to choose their own government through democratic elections, the country has become markedly more Islamic (see e.g., Brockett, 2011; Solmazturk, 2008; Tibi, 2009; Turan, 2006; Ünver, 2013).

Recent developments in Egypt have pointed to the same conclusion. Until 2011, Egypt was a relatively secular state with few pretensions of being democratic (while Turkey had been prior to the last decade a secular state with the façade of democracy), and the fall of Mubarak led to democratic elections in which the two strongly Islamist blocs – the Muslim Brotherhood and the Salafists – won more than 70% of the elected seats in Parliament and took power (see e.g., Farahat, 2011; Stock, 2012). In 2013, backed by a petition whose organizers, the Tamarod movement, claimed to have 22 million signatories, the military took power again (the only estimates of the number of signatories or supporters of the Tamarod movement come from the military and Tamarod itself) and established more or less the status quo ante, and although there are claims that one day elections will be held again, this does not seem likely to happen in the foreseeable future. One may call the military's reassertion of control a coup or something else, but it clearly was not done through normal democratic procedure. As with developments in Turkey, this similarly suggests that it is naïve to believe that, in Muslim countries at least, secularism and democracy necessarily go together or that the expression of national identity through democratic elections naturally motivates people to downplay the religious aspect of their identity. On the contrary, the pattern in at least some Muslim societies seems to be that democratic institutions reflecting popular voting strengthen the religious aspect of the state at the expense of its secular aspect, so that in such societies one might have to choose between secularism and democracy (or, alternatively, redefining democracy in such a way as to not directly reflect popular voting).

It seems that national identity in Muslim countries can be strengthened by expressions of religious identity, so that there is a perception that e.g., if a Turk is more of a Muslim, she/he is also more of a Turk. Many, if not most, Muslims apparently do not distinguish between being nationalist and being Islamist. Far from setting up their state in opposition to religious institutions, modern Muslim states seem to be using Islam as best they can to legitimize themselves, and this has become more important and complicated in recent times as the general trend toward democratic elections has grown stronger.

It is of course true that not all states dominated by Muslims clearly fit this pattern. One might identify states such as Malaysia, Bangladesh, and Albania as cases that better fit the Western model, where the establishment of democratic institutions has not resulted in significant popular support for Islamism. It is worth noting that these countries correspond much more closely to the Western ideal of the nation-state – the overwhelming majority of citizens belong to a particular language-based nationality, there are no significant conflicts with members of other language-based nationalities (as between the Turks and the Kurds in Turkey, a point discussed below), and there is no pan-national identity at stake (as in the case of Egypt and Arab nationalism). It may well be that the cases in which Muslims generally do not want to put their national identity clearly ahead of their religious identity are specifically those cases in which their national identity is not associated with an existing nation-state; this is a matter which needs to be investigated.

A fourth way in which the relationship between Islam and national identity has developed in a way counter to Western assumptions is in cases where Islam is used in an attempt to neutralize the distinction between different linguistic groups in the same country by referring to their common religion. Whether or not this puts religious identity in opposition to national identity depends upon whether one defines national identity in terms of language or in terms of citizenship – if national identity is defined in terms of language, then the idea is to subordinate national identity to religion in the sense of saying that common religion trumps different language, while if national identity is defined in terms of citizenship, the idea is to strengthen national identity by associating it with a common religious identity. To be sure, Western governments did try things like this in the past, most obviously the attempts by the

Austro-Hungarian government to hold their empire together by appealing to the common Catholicism of the different linguistic-national groups, but these attempts were completely unsuccessful. But thus far this is generally not the case in Muslim countries today – on the contrary, a crucial aspect of the rise of Islamic identity in Turkey today has been efforts in the last decade by Islamically oriented Turks and Kurds to bridge the gap between the different linguistic groups by emphasizing their common Islamic identity (see Sarigil and Fazlioglu, 2013). In fact, the rise of the AKP as the dominant party in Turkey coincided exactly with the end of the Kurdish–Turkish conflict, which took more than 35 000 lives and ended in 2000, with the AKP being founded in 2001 and taking almost 2/3 of the seats in the 2002 elections. Turkey appears to have solved its problem of having two linguistically divided nationalities, at least for the time being, by turning to Islamism. Similar motivations can be found for the appeal of Islamism in countries with radically mixed linguistic populations such as Iran, Pakistan, Indonesia, and Sudan, this in contrast to the limited appeal of Islamism in more prototypical nation-states like Malaysia, Bangladesh, and Albania. (To be sure, such tactics are by no means limited to Muslims – Tuttle (2005) shows how efforts to incorporate Tibet into China have been associated with appeals to their common Buddhist tradition.)

Fifth, in the last decade radical splits have developed between different Islamic factions, particularly Sunnis on one side and Shiites (and in Syria also Alawites) on the other side, most dramatically in Iraq and Syria but also in other countries such as Bahrain and Yemen. This split is occurring particularly in Arabic-speaking areas, although there are increasing tensions between these groups in other areas as well. To a significant extent the armed conflict in Arabic-speaking areas has become particularly serious in the last decade because non-Arab states, Iran and the United States, have materially helped the Arabic-speaking Shiites, who had been politically powerless in the area since the twelfth century. This created a more balanced playing field (viewed positively) and an arena for conflict (viewed negatively). Of course, the United States did not enter the arena in Iraq to help the Shiites there, but because they deposed the Sunni ruler Saddam Hussein. This action established a framework for democratic elections, which the Shiites – by far the largest group – would obviously win, and this was a predictable result of their involvement. But whatever outside powers have done, it is still undeniable that Arabic-speaking Sunnis and Arabic-speaking Shiites/Alawites are systematically killing each other because of their religious affiliation, and if Arab national identity is associated with speaking Arabic, this means that they are evidently treating religious identity as being more important than national identity.

But in fact it turns out that that Arab national identity is not, and has never been, associated only with speaking Arabic. The Arab League has defined Arab nationality as follows: "An Arab is a person whose language is Arabic, who lives in an Arabic-speaking country, who is in sympathy with the aspirations of the Arabic-speaking peoples." The assumption here is that having Arab nationality involves not only speaking Arabic (that is, a typical language-based criterion for nationality) but also a particular political orientation. Although this definition does not explicitly refer to religious affiliation, in practice the applicability of the term 'Arab' does appear to depend upon religion. Before the last decade, the only Arabic-speaking group that was more or less universally considered not to be Arab was Arabic-speaking Jews, that is, a group defined by religious affiliation (see e.g., Shenhav, 2006). If this were the only case of this type, it might be ascribed to something about Jews in particular as opposed to religion in general. However, there were also the cases of the Maronites of Lebanon, another religiously defined group for whom there was evidence that the overwhelming majority do not consider themselves to be Arabs (Khashan, 1990) – although this was mitigated by the fact that non-Maronites did not generally share this belief – and also Israeli Druze, another religious group, whose men serve in the Israeli army and whom the Israeli government does not officially consider to be Arabs.

But in the last decade, the cases of Arabic-speaking people of particular religious affiliations who are not considered to be Arabs have proliferated to the point where this can no longer be explained away as unrelated to religion, particularly in the context of conflicts between Sunnis, Shiites, and Alawites, which have made it undeniable that Arab nationality is directly tied to religion, specifically to Sunni Islam. The American invasion of Iraq in 2003 accelerated this process, and in the subsequent American-sponsored elections of January 2005, Shiite parties won a resounding victory. This was expected, given that the Arabic-speaking Shiites are 60% of the population of the country, but the Arabic-speaking Sunni minority, constituting 20% of the population, had been politically dominant since Iraq became independent in 1932. Indeed, Sunni Islam had been the politically dominant religion in what is now Iraqi territory since the seventh century (aside from a brief period under Mongol rule), so that the Shiite takeover was a radical challenge to the Arabic-speaking Sunnis' understanding of the natural political order of things. They responded by initiating a series of attacks against Shiite targets, which produced predictable responses, and on 6 April 2006, President Hosni Mubarak of Egypt (a Sunni, like almost all Egyptian Muslims) stated in a televised interview on al-Arabiyya that 'Shiites are mostly always loyal to Iran and not the countries where they live,' in effect excommunicating Arabic-speaking Shiites from the Arab nationality on the basis of their religion. As political scientist Vali Nasr interpreted this statement in an interview with *Der Spiegel* on 25 October 2006: "When President Hosni Mubarak of Egypt says that the Shiites are more loyal to Iran than their own countries, he is saying that the Shiites are not genuine Arabs, that they are somehow Iranian tools."

Since then, it has become common to refer to the different Arabic-speaking groups in Iraq as being 'Shiites' and 'Sunni Arabs.' For example, in the title of Mohammed M.A. Ahmed's 2009 book *America Unravels Iraq: Kurds, Shiites, and Sunni Arabs Compete for Supremacy*. Any random Google search will produce countless references of this type, contrasting 'Shiites' and 'Sunni Arabs' (but never 'Sunnis' and 'Shiite Arabs'). A similar situation has developed for Alawites in Syria, particularly since the beginning of the uprising against the Alawite regime of Bashir al-Assad in 2011, e.g., a video clip on YouTube entitled 'Syrian Sunni Arab citizen soldiers blow up Alawite outpost' [sic]. In connection to this, in a questionnaire study done in 2012 regarding how much different Arabic-speaking groups are perceived as being real Arabs, Ayyad (2014) found that Palestinians and Egyptians gave each other average Arabness ratings of 4.5 on a 5-point scale but rated Iraqi Shiites and Alawites as averaging lower

than 2, barely higher than Maronite Christians, Israeli Druze, Moroccan Jews, and Arabic-speaking Israeli Jews.

From these data, it appears that what is going on is that although Arab nationality is, in principle, defined in terms of the language that one speaks, in practice religion plays a significant role in that certain religious groups – Jews, Israeli Druze, Maronite Christians, Iraqi Shiites, and Alawites – are now widely considered to be excluded from Arab identity. Why these groups in particular? What all of these groups have in common, and what distinguishes them from other Arabic-speaking groups, is that they have all taken up weapons to fight against Arabic-speaking Sunnis. To be sure, this is not necessarily the reason which is overtly given in each case – it is usually stated in terms of loyalty to the Arab cause (like 'in sympathy with the aspirations of the Arabic-speaking peoples' in the definition of the Arab League). But there is apparently an implicit understanding that the Arab cause is the Sunni cause, that the aspirations of the Arabic-speaking people are for Sunni rule everywhere in Arabic-speaking territory, whether or not Sunnis are the local majority. To be sure, this is specifically the Sunni understanding of Arab identity – it is much less widespread among non-Sunnis. But Sunnis are the overwhelming majority of Arabic speakers overall, and so it is their understanding that basically controls public discourse; non-Sunnis never deny the Arab identity of Arabic-speaking Sunnis – at most they try to assert that they too are Arabs.

A final point to be made with regard to the effect of Islam upon the understanding of the relationship between nationality and religion today is that recent developments in contacts with Muslims have motivated some Westerners to adopt a political worldview which is in some sense parallel to that of Muslims in terms of assuming that religious identity as a Christian strengthens one's national identity as a citizen of a state politically dominated by Christians. The 9/11 attacks and smaller-scale attacks by Muslims against Western targets, as well as demands for accommodations by some Muslim immigrants to Western countries, have produced an anti-Muslim backlash by many Westerners, which has taken the form of politically rallying around Christianity – there were of course elements of Western society which in any case would have taken such a view, but there is no question that behavior by Muslims has increased both the number of Westerners who feel this way and the intensity of their feelings (see Goldberg, 2007). George Bush instinctively used the word 'Crusade' in speeches on the day of the 9/11 attacks and subsequent times to refer to military actions the United States would take to prevent further attacks of this type, and the connection to earlier conflicts with Muslims was undeniable and resonated with many Americans and Western Christians. Samuel Huntington's 1996 book *The Clash of Civilizations and the Remaking of World Order* was interpreted as prophetic in this context, and although Huntington used the term 'Western' rather than 'Christian' or 'Protestant/Catholic' to define what he saw as his own civilization, the fact that he used religious terms to define both the civilization which Western civilization is in direct conflict with at the present time and also the civilization which it had been in direct conflict with immediately before ('Muslim' and 'Orthodox' respectively) strongly implied that in terms of clashes, the really relevant parameter defining Western civilization is Western Christianity.

Recent events have also suggested that radicalization of any religion can be used to serve the cause of a nation associated with that religion, or at least to do something that radicals will perceive as serving such a national cause (see Greenfeld, 1996). Arabs, for example, appear to have been motivated to promote world-wide Islam by the fact that for historical reasons they can claim that Islam is 'their' religion and that the goals of Arab nationalism should be adopted by the *'umma* in general. Perhaps the most graphic example of this in the last decade has been the genocidal policies of the Arab government of Sudan toward the non-Arab Muslims of Darfur, which has resulted in about half a million civilian deaths, supported by an ideology according to which, although the non-Arabs of Darfur are Muslims, they are not as good Muslims as the Arabs are, so that it is in the interests of the Muslim *'umma* that they be subdued by whatever means necessary. As Gerard Prunier formulated this thinking, "Darfur was poor and backward because it was insufficiently Arabized. It had missed out in the great adhesion to the Muslim *'umma* because its Islam was primitive and insufficiently Arabic" (Prunier, 2005: p. 162), and accordingly in 2007 Osama bin-Laden called for a jihad in Darfur against Sunni Muslim non-Arabs in support of the Khartoum government. Similarly, as the conflict between Sunni and Shia Islam has heated up in recent years, it is natural that Turkey and Iran would try to increase their national influence by presenting themselves as the champions of Sunni and Shia Islam respectively, Turkey by emphasizing the role of the Turks in their Ottoman and post-Ottoman guise, Iran by virtue of being the only Shia power (see Louër, 2008). For that matter, perhaps George Bush the evangelical Christian was in initiating a Crusade in response to the 9/11 attacks actually motivated by George Bush the oil man, who recognized his country's national need for oil.

In the same way, although Jewish nationalism was originally not only secularist but opposed by the religious Jewish establishment, the situation has changed radically since the capture of the Old City of Jerusalem in 1967. On the one hand, religious Jews in Israel have (with the exception of the Naturei Karta, who remain anti-Zionist on the grounds that the messiah has evidently not yet come) not only embraced Zionism but have even managed to change the understanding of what Zionism is – whereas Zionism originally called for *a* Jewish state without any particular borders, it is now widely understood to require the inclusion in this state of areas beyond the 1967 borders of the state, particularly those deemed of religious significance to Judaism. This view motivates the establishment of Jewish settlements in these areas (increasingly focusing on certain areas in the West Bank, excluding Gaza). While this might appear to be a case of the religious tail wagging the nationalist dog, things are not so clear. Secular Jewish nationalists, opposed to territorial concessions to the Palestinians, have taken advantage of the situation by forming political alliances with representatives of the settler movement. Indeed, considering the fact that only one-third of Israeli Jews define themselves as being religious, and the expense and danger as well as the external criticism resulting from the settler movement, it is clear that many Israeli Jews must feel a non-religious, presumably nationalist, reason for supporting this movement. This is particularly clear in the case of Avigdor Lieberman's avowedly secular Yisrael Beiteinu party, supported particularly by Russian immigrants. In one way or another, this thinking pervades Israeli politics, a striking

recent example being the alliance instrumental in forming the present government between Yair Lapid's centrist Yesh Atid party, representing the secular middle class, and Naftali Bennett's HaBayit HaYehudi party, representing religious Zionism. While such alliances may seem bizarre or even incomprehensible to non-Israelis, they illustrate the extent to which it is not clear in Israel whether nationalism is the tool of religion or whether the reverse is the case.

One of the most striking examples of religion being used as a tool for nationalism involves the Lord's Resistance Army (LRA), a rebel group originally formed in Uganda in order to fight against the army of the national government there. The ostensible goal of the LRA has been to establish a Christian theocratic state based upon the Ten Commandments, and its leader Joseph Kony claims to be a spirit medium who reveals God's word. The depredations of the LRA are widely known today, but what is much less known is the relationship between the group and Acholi nationalism, the Acholis being a Nilotic group constituting about 5% of the population of Uganda whose homeland is in the north–central part of the country and whose members have constituted the overwhelming majority of those fighting for the LRA. The roots of the LRA can be traced back to British colonial policy in Uganda, which resulted in the armed forces, including the officers' corps, having a radically disproportionate number of Acholis, a situation which continued after decolonization. This resulted in significant tensions between the largely Acholi military and non-Acholi rulers of Uganda (the Kakwa Idi Amin (ruled 1971–79) and the Lango Milton Obote (ruled 1979–85)), including purges against Acholi officers, leading to a coup in July 1985 led by two Acholi officers, Gasilio Olara-Okello and Tito Okello. Soon after, in January 1986, the National Resistance Army (NRA), led by the Banyankole Yoweri Museveni, overthrew the Acholi clique, and Museveni has remained in power to the present day. But the Acholi soldiers did not give up the struggle – rather, they reconstituted themselves as the Uganda People's Defense Army (UPDA) and attempted to evict the NRA from northern Uganda. Although the UPDA began to run out of weapons and ammunition within a year, Acholi nationalism quickly took a new form – the Christian faith healer Alice Aum, who claimed to be possessed by the Holy Spirit Lakwena, founded the Holy Spirit Movement, a military organization which fought based upon Christian principles (singing while fighting and not taking cover), and this movement drew the most dedicated Acholi fighters from the UPDA. Aum soon gave up the struggle and fled to Kenya, but beginning in April 1987, Joseph Kony organized the Lord's Salvation Army, later the LRA, made up overwhelmingly of Acholis, based upon Aum's ideas, and they began to fight a guerrilla war against the NRA, and eventually against other groups that opposed them. Failing to make significant progress against the NRA, the LRA's main target became other Acholis, particularly for the purposes of kidnapping children to serve in their army. Nevertheless, throughout its history, the LRA's leaders and followers have always understood that they are fighting for the Acholi people, regardless of whether or not other Acholis support them and their actions. Religious – specifically Christian – fervor has played a crucial role in convincing the members of the LRA of the rightness of their actions and given them the courage to risk death and reject normal human morality (see Le Sage, 2011; Noll, 2006; van Acker, 2004).

A strikingly similar case is that of the Taliban and Pashtun nationalism. The Pashtuns constitute about a third of the population of Afghanistan and about 15% of the population of Pakistan, and prior to the Soviet invasion of Afghanistan in 1979 they had been the politically dominant group in Afghanistan for hundreds of years. After the Soviets withdrew in 1989 and the communist government they had installed fell in 1992, the different Afghan political parties reached an agreement, known as the Peshawar Accords, which created the Islamic State of Afghanistan and an interim government representing different ethnic groups. The situation was still unstable, however, and the Taliban, which had begun to develop in 1991 in the Pashtun areas of southern Afghanistan based upon a radical fundamentalist interpretation of Islam that had been spread by the mujahedeen who had fought against the Soviets, soon spread their influence, drawing a disproportionate number of recruits from the Pashtuns. They began military operations in 1994 and captured Kabul in 1996, establishing the Islamic Emirate of Afghanistan, but the conflict continued, as the deposed leaders of the Islamic State of Afghanistan reconstituted their forces and formed the Northern Alliance to fight against the Taliban. The Northern Alliance was initially too weak to defeat the Taliban, but aided by the American invasion of Afghanistan in 2001, they were able to seize control of the central government, although they have still not managed to secure the entire country. Although in principle neither the Taliban nor the Northern Alliance were restricted to particular ethnic groups but differed rather in their interpretations of Islam, with the Taliban adopting a much more radical fundamentalist version, in practice the Taliban has been overwhelmingly Pashtun while the Northern Alliance was composed of other groups – Tajiks, Uzbeks, Hazaras, and other groups, but with very few Pashtuns compared to their share of the overall population of Afghanistan. The rise of the Taliban can therefore be understood as a radicalization of Islam by elements of the Pashtun community in an effort to restore the Pashtuns to their traditional position of political dominance in Afghanistan, just as the rise of the LRA in Uganda was the result of the radicalization of Acholi soldiers who feared that they would lose their influence under the Museveni regime. As the Taliban has lost influence in the last decade, Pashtuns have increasingly turned to cooperating with the central government (for example, Hamid Karzai, the President of Afghanistan since 2001, is a Pashtun), but the story of the Taliban remains as a recent example of how religion can be used in an attempt to further national interests in the modern world. Of course, in all of these cases (Arab, Jewish, Acholi, and Pashtun) and similar ones, many members of the national group would deny that this use of religion is consistent with the essence, interests, or values of the nationality, but there are members of the nationality who have a different interpretation of the situation and use religion as a way to direct and motivate national endeavors in a way that they see fit.

Nationalism and religion interact today in myriad ways in different contexts, and to be realistic this is likely to continue in the indefinite future, although there will certainly be trends in how they interact. The clearest trend in this respect is that the interaction between nationalism and religion is increasingly being played out in the politics of democratic institutions,

as religiously inclined people are becoming increasingly sophisticated at playing the game of democracy and maneuvering to improve their position. This can be seen not only in the rise of, for example, the religious right in the United States, the AKP in Turkey, the BJP in India, and religious parties in Israel, but also in the manner in which religious fundamentalists in countries like Egypt and Syria used initially secular street protests, which created the appearance of popular resistance to a non-democratic government, as a means of destabilizing that government for the purposes of eventually taking control of the country. But it is not only religious people who are coming to grips with this reality, as governments and non-religious people are trying to figure out how to deal politically with the situation – for example, secular Israelis in choosing which secular party to vote for will naturally consider statements from secular party leaders regarding whether or not they will sit in a government including one or another religious party, and they may remember whether or not particular leaders have kept such promises in the past (see e.g., articles in Foret and Itçaina, 2012 about the political role of religion in Europe today). But at the same time that religion is coming to be understood as a normal part of democracy, it is also coming to have an increasingly prominent role in motivating violence, which can undermine and circumvent democracy, as religiously motivated people may believe in a law that transcends laws established by democratic institutions, and they may not particularly fear human punishment for transgressing these laws. But whereas in earlier times such efforts were motivated by purely religious conviction, in the present day there is an increasing tendency to use them to advance national interests in the eyes of the actor and to circumvent democratic processes in determining national policy.

Abstract

The phenomenology of religion has uneven relationships to philosophical phenomenology and social-scientific research. Descriptive, analytic, and social phenomenological approaches can be distinguished as ideal types. Descriptive phenomenology elides the philosophical distinction between existence and appearances, thereby bypassing issues of ontology and epistemology. Nevertheless, historical and ethnographic descriptions have been important to the development of the two other approaches, and they yield substantive studies of religion. Analytic phenomenology encompasses structural, hermeneutic, and formal possibilities. Formal phenomenology and Schütz's lifeworldly extension clarified the basis for a social phenomenology of religion, both on a general basis and in comparative and historical phenomenology.

Introduction

The phenomenology of religion refers to a range of approaches that address religion as apprehended, religious experience, and religious worldviews. These methods tend to emphasize understanding religious phenomena according to the subjective meanings and actions of individuals engaging in religious experience, rather than on the basis of neutral observations. Approaches to the phenomenology of religion can be mapped in relation to three ideal-typical alternatives: (1) *Descriptive* attempts to identify the essence of religion in empirical phenomena and to develop typologies of religiosity based on essential characteristics; (2) *Analytical* efforts to use explicit methodologies to develop accounts of phenomena; and (3) *Social* accounts of religious phenomena in their lifeworldly manifestations. Each of these approaches has developed over time (1) through reflexive engagement with issues in the phenomenology of religion itself, and (2) often through engagement with other fields of inquiry such as philosophy, anthropology, history, psychology, and sociology.

The Descriptive Approach

During the eighteenth and nineteenth centuries, phenomenology as a distinctive theme emerged at the intersection of philosophy and religion in the works of Lambert, Kant, and Hegel as they grappled with understanding consciousness and lived experience (Knoblauch, 2001). In the nineteenth century, religious studies came into its own as a distinctive enterprise, in the German *Religionswissenschaft* – the analytic science of religion founded by Max Müller. Differentiated from theology and dogmatics based on anthropological and historical interests, it became known in the United Kingdom under the rubric of comparative religion and in the United States as the history of religions. However, like subsequent formulations of religious studies as an interdisciplinary enterprise, the *Religionswissenschaft* lacked any single established methodology, and its practitioners drew freely from archeological, ethnographic, and historical approaches. Their generic project was to use descriptions of religious phenomena to create typologies of subjective experience through systematic, nonreductionist, and comparative inquiry.

Features of the descriptive phenomenology of religion can be found in the works of William James and Emile Durkheim, though neither construed himself as a phenomenologist. Both authors drew on empirical observations from disparate sources. Durkheim's (1995 [1912]) characterization of 'collective effervescence' – the shared psychic energy experienced in moments of ritualized communion – and James's (1997 [1902]) concepts of the 'sick soul' and 'mysticism' both involved efforts to capture and catalog religious experience in its basic features. Results of these works were expected to be applicable across place, time, and culture.

Two other scholars are especially notable for their more self-consciously phenomenological descriptions. In the *Idea of the Holy*, Rudolf Otto (1923 [1917]) sought to define and describe a specific kind of religious phenomenon. Characteristic of the descriptive approach, Otto avoided normative assessment of religious experience. Instead, he sought to identify the experience of the 'holy,' devoid of any commonly assumed moral underpinnings. For Otto, the 'numinous,' or experience of the divine, was an empirically given and fundamental feature of religion. He held that, though universal, experience of the holy transpires in myriad ways. Variations in specific historical instances do not contradict the numinous as a single irreducible feature of religious experience, he argued. Rather, each variation can be identified as a manifestation of the numinous as a fundamental phenomenon.

Gerardus van der Leeuw's (1963a [1933]) *Religion in Essence and Manifestation* is also emblematic of the descriptive approach. Van der Leeuw created a broad basis for understanding religious phenomena by systematically considering their forms, for example, seeking to identify the essence of angels, power, and sacrifice by comparison across religious traditions.

The descriptive phenomenological project was rigorous, but like nineteenth-century anthropological work, it was largely ahistorical and simultaneously historicist in its avoidance of engagement with epistemological or methodological issues. There was an underlying assumption that by basing analysis on diverse observations, the phenomenology of religion could

divorce itself from the biases and influences of place, time, and method. From diverse scholarly standpoints and at various junctures over the course of the twentieth century, such an assumption came to be regarded as unreflexive and naive.

Analytical Approaches to Phenomenology

Analytical approaches to phenomenology give increased emphasis to methodological and theoretical frameworks. They largely emerged in reaction to the shortcomings of descriptive phenomenology. However, analytical perspectives did not replace descriptive phenomenology. Some authors, intentionally or unintentionally, blended description and analysis. Nor were analytic approaches all of a piece (or equally engaged in the investigation of religion). The major analytical tendencies that emerged can be described in relation to three general approaches: (1) structuralist phenomenology, (2) hermeneutics, and (3) formal phenomenology.

Structuralist Phenomenology

Structuralist phenomenology involves an attempt to focus on observable phenomena, often seeking generalization through induction. This perspective can be seen in scholars such as van der Leeuw (1963a), whose descriptive efforts led him toward categorization of religious phenomena, and Mircea Eliade (1954; 1959) who, for example in *The Sacred and The Profane*, identified a vast array of cases that incorporate a center to sacred space, the *axis mundi*. After analyzing each case in relation to the others, Eliade deduced general rules or 'law-like' systems. The generalizations were then imposed back onto each case as the true meaning or essence of the phenomenon. In this approach, as with Durkheim, experience and meaning were eclipsed, and phenomenology began to approximate other movements toward structuralist analysis of social forms independently of meaning.

Hermeneutics

An alternative approach, hermeneutics, looks to the distinctive ways of understanding and meanings that individuals employ to apprehend and act upon the worlds that they experience. Hermeneutics as a practice is, of course, deeply grounded in the analysis of religious texts. However, in the late eighteenth century, Schleiermacher and, in the early twentieth century, Dilthey shifted hermeneutics into the broader analysis of social and historical texts. Max Weber (1978 [1922]) adopted Dilthey's principle of *verstehen* (lit. 'understanding'; Dilthey used it to signify the analyst's effort to make sense of the perspective that actors have on their situations and actions), and tied it methodologically to the construction of ideal types, yielding a quasi-phenomenological sociology of subjectively meaningful action and its organizational and processual correlates. Weber worked to preserve the significance of subjectivity and meaning that are lost in structural reduction to social forms. However, he did not seek to reduce all meaningful phenomena to their historical specificities, which would remove any hope of generalizability. He therefore employed ideal types to ferret out the degree to which a given case approximated various generic structures of meaning. Thus, a phenomenon such as 'the Protestant Ethic' could be identified as an ideal type, or general sociohistorical model, even if it is never observed completely in a single instance but only in sectarian alternatives that approximated it in one way or another, and to a greater or lesser degree.

Formal Phenomenology

Early descriptive approaches to phenomenology involved efforts to apprehend appearances, and thereby to identify the properties of those things apprehended, posited to have ontological existences on the basis of which perception as phenomena was possible. Modern phenomenologists, by contrast, took more seriously the problem of phenomenal appearances, and their formal turn involved interrogating the character of consciousness that makes sensate appearances possible (for an overview, see Smith, 2011). In modern formal phenomenology, the point of departure is similar to that of social hermeneutics, centered on individuals' understandings of their own and others' meaningful actions. However, the strong formal move, taken by Husserl, was to ground all knowledge in understanding the character of subjective consciousness per se, and to do so through an 'epoché' that 'brackets' the contents of all perceptions and sensations and any assumptions concerning the existence of external objects (e.g., a 'red chair') that might conventionally be taken for granted as giving rise to them. In this 'transcendental reduction,' the objects of perception are no longer assumed to reflect any ontological status. Contrary to the structuralist effort to identify the essential character of experiences (or even, in looser phenomenologies, the objects themselves), Husserl's formal phenomenological approach takes consciousness as the object of phenomenological investigation, most successfully in his *Phenomenology of Internal Time Consciousness* (1964 [1928]).

Scholars responded to Husserl's phenomenology of consciousness by either attempting to further his investigations or criticizing his conclusions as untenable. For social inquiry, the most significant development came in the work of Alfred Schütz, who argued that a social phenomenology could only proceed after first clarifying the nature of consciousness via Husserl's transcendental investigations. As Husserl (1964) showed, individual consciousness transpires as a stream of temporally sequential events. However, Schütz (1967) noted, the cognized and constructed world that an individual experiences in the 'natural attitude' in effect disappears in Husserl's transcendental reduction, leaving no basis for a specifically social phenomenology. Put differently, individuals generally experience the world that they apprehend, including the setting, other people, families, and organizations, as really being there. Thus, a social phenomenology may be based upon Husserl's transcendental investigations of consciousness, but it must proceed by investigating the structure of the lifeworld as apprehended by the individual under the dispensation of the natural attitude, in which the historicity and social relations of the world that appear in consciousness are taken to be real.

The other analytical approaches to phenomenology (not to mention descriptive phenomenology) were not fully

phenomenological, at least in the modern philosophical sense of the term. For its part, Husserl's formal turn in phenomenology occluded any investigation of the objects of consciousness, including ones deemed 'religious.'

Social Phenomenology and Religion

Prior to Schütz, most phenomenologically inspired study of religion took place within fields that eventually became consolidated as the (inter)discipline of Religious Studies, or they were underwritten by an ethnographic anthropology. The exceptions were Emile Durkheim, whose study of religion, however, was only implicitly phenomenological, and Max Weber, whose emphasis on meaningful action opened up the possibility of a comparative hermeneutic sociology of religion. Indeed, Weber's monumental comparative sociology of the world religions and his famous studies of the Protestant ethic can be read in a phenomenological light.

Here, Schütz's intervention was important. By moving from the pure, transcendental phenomenology of Husserl to a phenomenology in the 'natural attitude' of the individual located in the natural and social world, Schütz (1967 [1932]) was able to offer a phenomenological critique of Weber, whom he regarded as offering an observer's typification of meaning, action, and action structures rather than a phenomenology of the social world radiating out from an actor's consciousness. Schütz, with his collaborator Thomas Luckmann (1973), in turn offered a formal phenomenology of the lifeworld. However, Schütz himself only touched upon the subject of religion in the most glancing ways. His project thus left unfulfilled the possibility of a phenomenologically grounded social-scientific approach to religion.

Since Schütz, a specifically phenomenological social-scientific approach to religion has been taken up in two interconnected programs: (1) a general phenomenology of religious experience and meaning, and (2) an historical and comparative phenomenology of religion in relation to alternative patterns of social action and organization.

The General Phenomenology of Religion

As early as 1963, Thomas Luckmann and Peter Berger began to connect the study of religion to issues in the sociology of knowledge, themselves amenable to a phenomenological approach. From there, individually and together, the two scholars elaborated a general approach to the social phenomenology of religion, based in what was to become their extension of phenomenology, designated as the 'social construction of reality'.

Luckmann's (1967 [1963]) analysis locates religion phenomenologically in ways directly tethered to the work of Schütz, but moving beyond it. He argued that religion is, at base, a symbolic universe of meaning, and that concrete historical forms of religion – as church, or sect, or ancestor worship, or so forth – are simply instantiations of that more general phenomenon. Yet religion is not simply one of many such symbolic universes. For Luckmann, it is a primordial one connected to the social formation of the self. Religion, phenomenologically understood, is a fundamental and pervasive social phenomenon, but on a somewhat different basis than that argued by Durkheim. For Luckmann, a transcendent and publicly objectivated worldview, constructed in important ways as a sacred cosmos maintained through ritual action, is the ultimate basis of selfhood. From this phenomenological point of departure, Luckmann was able to theorize about the general character of religious institutions and about modernizing societal developments of social differentiation and 'secularization,' in relation to both religious institutions and individual religiosity.

In turn, Peter Berger (1967, 1969) grounded a general sociological analysis of religion both in relation to classic phenomenological scholars on religion such as van der Leeuw or Eliade, and in the more formal but nonreligious social phenomenology of Schütz (Schütz, 1967; Schütz and Luckmann, 1973). On this basis, Berger especially developed the general phenomenological analysis of religion's capacity to locate a sacred cosmos that simultaneously grounds the social world ontologically and provides a legitimation of it in everyday life, especially important when the reality of that life is challenged by 'marginal situations' such as death or war that might otherwise be taken to throw the otherwise taken-for-granted social world into doubt. Like Luckmann, Berger was particularly concerned with 'secularization' and the rise of social orders grounded outside religion.

The scholarship of Luckmann and Berger provide a key bridge that links the explicitly social phenomenology of Schütz with the classic phenomenological treatments of religion. Their work thus infuses general social theory with a phenomenology of religion.

The Comparative and Historical Phenomenology of Religion

Social science is concerned not only with general accounts of the social but also with the specificities of social constructions of self and identities, meaningful patterns of social action, institutions, organizations, and movements. Thus, a general social phenomenology of religion would need to be elaborated in relation to the substantive constructions of historically given social worlds in order to connect more richly with social-scientific analysis. Already, Berger and Luckmann's interests in modernity and secularization signal this possibility. Similarly, Luckmann (1967: 50) cautioned against defining religion as dealing with the 'supernatural,' and this point accords with much empirical work on religion, from that of Max Weber onward, which demonstrates that the focus of religious sacrality can become oriented to the most diverse loci of identity construction and social action – from mystical experience to ascetic engagement in economic action.

Thus, insofar as phenomenology is concerned with the lifeworld and its myriad possibilities of instantiation, a general social phenomenology of religion is rightly to be supplanted by a comparative phenomenology of lifeworlds. Such a project has been pursued in historicist and ethnographic studies. In addition, Hall (1977; 1981) called for a comparative phenomenology of the lifeworld, and he (Hall, 2009) began to specify this approach in relation to religion by describing a general analytic framework for phenomenological comparison and developmental historical analysis of forms of social process and organization (bureaucracy, competition, community, etc.) in relation to a phenomenology of temporally specified social

action (in the here-and-now, diachronic, and apocalyptic orientations). Such an approach offers a basis to extend the phenomenology of religion in ways that affirm Luckmann's concern with moving analysis beyond the supernatural, at the same time, linking with Weber's recognition that sacrality can be directed to the most diverse spheres of social life, even to economically rational action.

Conclusion

There is no single methodological or epistemological foundation for the phenomenology of religion. Even the major alternatives – descriptive, analytical, and social approaches – are neither mutually exclusive nor contradictory. Rather, they amount to strategies for engaging phenomenological investigation in relation to understandings of essences and lifeworldly enactments, all in relation to social theory. Moreover, the alternative approaches can increasingly be understood in relation to one another. Scholars draw on descriptive, analytical, and social approaches to the phenomenology of religion in varying degrees and complex articulations. Thus, the phenomenology of religion, grounded in an understanding of structures of consciousness and the lifeworld, offers a way of mapping religiosity in its social formations that should become increasingly important to the pursuit of diverse research programs.

Abstract

Although psychiatry and religion have a long and troubled history with each other, there are good reasons for a rapprochement. Empirical studies have shown that religion can be both a resource for the mentally ill and a source of problems. Patients also generally prefer religiously sensitive care. In recent years, the field has made promising theoretical advances, including work in the areas of religious coping and attachment. Research studies have also underscored the value of spiritually integrated approaches to psychiatric diagnosis and treatment. The article concludes with a description of promising new directions for theory and practice in psychiatry and religion.

Psychiatry and Religion: A Long and Complicated History

Psychiatry and religion have a long and complicated relationship with each other. In ancient times, signs of mental disorder were understood as reflections of imbalanced body fluids, supernatural agents, or a troubled relationship between the individual and God. During the Middle Ages and early Modern period in Europe, mental illness was often interpreted as a manifestation of diabolical forces, evil spirits, or possession. The Modern era and Enlightenment heralded a shift from harsh religious explanations of madness to more biological interpretations and more humane approaches to treatment.

In the twentieth century, the relationship between psychiatry and religion was strongly influenced by Freud's psychological theories. Freud (1927) famously conceptualized religion as a response to childish feelings of helplessness in a world of chaotic forces and need for a father-figure who would provide protection and care. He maintained that religion was illusory and he suggested that it would be better for individuals to face the realities of life rather than to rely on unrealistic, childlike wishes of having a God. Freud's harsh perspective on religion was tempered by some of his followers, such as Jung, Rizzuto, and Winnicott. Jung treated religious beliefs and behaviors in a more positive manner and provided a psychological understanding of terms such as 'soul,' 'sacred,' 'God,' 'transcendence,' and 'evil' (Palmer, 1997). Rizzuto (1979) outlined how the development of the relationship with a primary object (such as a parent) correlates with the transitional object that represents God. She took detailed life histories and spiritual histories from her patients to learn more about their understandings of God. Winnicott (1971) treated 'illusion' as a developmentally necessary bridge between the infant's self-absorption and later involvement in reality. He viewed illusion as an essential part of human experience by which humans meet their deeper needs for artistic, symbolic, and religious meaning and involvement. He posited that religion can be viewed as a transitional phenomenon, neither subjective nor objective. Rather than automatically diminishing or dismissing religious experience as subjective or hallucinatory, merely because physical or objective evidence is absent, Winnicott's writings set the stage for a more constructive view of religion.

In spite of these more benevolent psychiatric perspectives on religion, some tension remains between psychiatry and religious viewpoints (Shuman, 2009). The tension is, in part, a reflection of psychiatric theory critical of religion, such as the work of Freud. However, other factors contribute to this antagonism. Psychiatrists, like other mental health professionals, tend to be less religious than their patients. For instance, 38% of psychiatrists sampled from the American Psychiatric Association reported that religion is very important to them in comparison with 58% of the American population (Shafranske, 2000). As a result of their relatively lower religiousness, psychiatrists may underestimate the salience of religion among patients and fail to appreciate or attend to the religious significance of illness to the patient and family. Furthermore, only 27% of US psychiatry residency programs train residents to work with religious patients (Bowman, 2009); therefore US psychiatrists may be ill-equipped to deal with religious issues arising in treatment (Curlin et al., 2005). In addition, psychiatrists may lack knowledge about faith-based systems that offer resources for treatment, religious and spiritual factors that exacerbate psychiatric symptoms, and religious beliefs and practices that affect treatment acceptance. Psychiatrists may be wary about discussing religion for other reasons as well, such as time constraints, fears that the patient will not be receptive, or fear of being accused of violating boundaries.

Finally, although psychiatry and religion share a concern with understanding and enhancing the health and well-being of people, they offer at least somewhat different perspectives on the causes and remedies of illness. Tensions between psychiatry and religion can grow out of these differences in world views

(Shuman, 2009; Hughes and Wintrob, 2000). For example, the medical community uses the diagnosis–treatment approach to illness, whereas many faith communities hold that symptoms originate from taboo violations and resultant guilt, and believe that confession is the appropriate response. The world views of psychiatry and religion are not necessarily contradictory or incompatible. Psychiatrists and clergy alike often keep both naturalistic and religious explanations in mind, and have used both understandings to formulate approaches to treatment and change. However, the world views of psychiatry and religion can become polarized, and when they do, antagonism and mistrust may occur.

The implications of this tension are significant. Patients seeking psychiatric care may fear being labeled neurotic, pathological, or even psychotic for their religious beliefs. As a result, they may not raise religious issues during psychiatric treatment. Some religious individuals may decline or discontinue psychiatric treatment out of concern that the plausibility of their faith may be challenged or threatened. In this vein, Keating and Fretz (1990) found that more religiously committed patients had more reservations about therapy, fearing that the therapist would ignore spiritual concerns, find them bizarre, reject the idea of communicating with a higher power, or assume that the patient shared the therapist's own religious beliefs. Psychiatrists and clergy may also keep their distance from each other. For example, clergy refer less than 10% of their clients to mental health clinicians; and mental health professionals refer even fewer of their patients to clergy (Mollica et al., 1986; Larson et al., 1988).

Rationale for Rapprochement between Psychiatry and Religion

Even though there are significant historically based tensions between psychiatry and religion, there are also strong empirically based reasons for a closer working relationship between these two domains. The need for rapprochement is rooted in the centrality of religion as a cultural institution, and because the mentally ill often use religion as a resource. These conditions make sensitivity to religious factors an ethical mandate for psychiatrists.

Religious beliefs, practices, and communities are deeply interwoven into the cultural fabric of the United States and other nations in the world. In the United States, for example, over 147 million people are members of religious congregations, and there are approximately 335 000 congregations in the United States (Lindner, 2010). According to the Pew US Religious Landscape Survey (2008), 58% of Americans report that they pray daily, 74% believe in life after death, 68% believe in angels and demons, 59% believe in hell, and 57% agree that it is necessary to believe in God to be moral and have good values. It is important to recognize that religion in the United States is dominated by various denominations of Christianity, although the culture is becoming increasingly pluralistic religiously. Within other countries, religion takes different forms, but it remains a critical, defining aspect of these cultures. Psychiatry recognizes that the development and course of mental illness cannot be understood outside of its larger cultural context. Religion is one key ingredient of this context (Pargament et al., 2013).

Religious beliefs and practices are also common among people with mental illness (see Mohr, 2013, for review). Kroll and Sheehan (1989) studied 52 psychiatric inpatients in Minnesota and found that 94% believed in God, 67% in the devil, 53% prayed or consulted the Bible, and 51% attended church weekly. In a survey of the alternative health practices of people with serious mental illness (SMI), religious/spiritual activities (50%) and meditation (40%) were the most frequently reported practices (Russinova et al., 2002). Elsewhere, Pieper (2004) studied 118 patients in a Protestant mental hospital in the Netherlands, and found that 92% participated regularly in private religious activities and religious services.

Many patients with mental illness indicate that religion offers valuable resources in the process of coping with their major stressors. Tepper et al. (2001) reported that 80% of a sample of 406 psychiatric outpatients with SMI in Los Angeles used religion to cope. In a comparative study of European psychiatric patients and a nonpsychiatric control group, Neeleman and Lewis (1994) found that the psychiatric patients reported a larger number of religious beliefs and practices that offered comfort during stressful life experiences. Religious professionals are another resource for people with mental illness. SMI individuals are as likely to seek treatment from clergy as from a mental health professional (Larson et al., 1988). It is important to add that religion can serve as a resource to caregivers of SMI patients. In a survey of caregivers to people with SMI, many participants reported that God is a source of comfort and strength (Murray-Swank, 2006).

There are ethical mandates to consider religion when providing psychiatric care (American Psychiatric Association Principles of Medical Ethics, 2013). For example, a committee of the American Psychiatric Association (2006) stated that: "Psychiatrists should foster recovery by making treatment decisions with patients in ways that respect and take into meaningful consideration their cultural, religious/spiritual, and personal ideals." Some writers have cautioned against health professionals overstepping their boundaries by addressing religious issues in the context of treatment (Sloan et al., 1999). They maintain that clergy are better suited than healthcare professionals to manage patients' spiritual concerns. Ethical standards in psychiatry, however, explicitly attend to these risks: "Psychiatrists should not impose their own religious/spiritual, antireligious/spiritual, or other values, beliefs and world views on their patients, nor substitute such commitments or religious/spiritual rituals for professionally accepted diagnostic methods or therapeutic practice" (American Psychiatric Association, 2006).

Religion Is Related to Health and Well-Being

Religion can serve a number of valuable psychological functions for people with mental illness. In one project, Mohr et al. (2006) found that among Swiss schizophrenia patients religion provided a number of functions, such as hope, comfort, meaning of life, enjoyment of life, love, compassion, self-respect, and self-confidence; and one-third

of these patients reported that they actually received social support from a religious community. In a study of 115 psychiatric outpatients in Geneva, Mohr et al. (2010) found that people who accessed positive religious coping resources experienced fewer negative symptoms and better social adaptation and quality of life 3 years later. These findings have been mirrored in other investigations of people with mental illness, in which higher levels of religiousness have been associated with the provision of meaning, hope, peace, and comfort (e.g., Fallot, 2007; Kelly and Gamble, 2005).

Several studies have shown that higher levels of religious commitment and involvement are associated with lower prevalence of mental illness and more favorable mental health outcomes (Koenig et al., 2012; Shreve-Neiger and Edelstein, 2004). Religiousness has been robustly linked with lower risk of substance abuse (Johnson, 2013) and successful recovery (Simoni et al., 2002; Pence et al., 2008). Religion can provide patients with guidelines for living a sober life, a sense of power through identification with a larger spiritual force, and a new healthier source of meaning and purpose. In addition, religious commitment may lower suicide rates (Huguelet et al., 2007). Huguelet et al. (2009) reported that one-third of their cases of people with SMI believed that religion offered protection against suicide attempts by providing meaning in life, a way of coping with despair, ethical condemnation of suicide, and positive religious experiences. Studies also suggest that the involvement of clergy in patient care results in increased patient satisfaction, increased medical knowledge, and improved treatment compliance (Parkum, 1985; Saunders and Kong, 1983; Bay et al., 2008; Iler et al., 2001). Finally, in contrast to the view that religion interferes with treatment adherence, one study of 52 patients with psychosis found that religiousness was associated with greater adherence to medication (Kirov et al., 1998). Similarly, Harris et al. (2006) reported that among those with SMI, religious attendance and importance of religious beliefs were both positively correlated with outpatient mental health service use and medication use.

Mental Illness Can Be Associated with Problematic Forms of Religiousness

Mental illness impacts people not only psychologically, socially, and physically, but spiritually as well. A significant number of people experience religious struggles as a result of their illness. Religious struggles reflect tension and doubt about spiritual issues within oneself, with a religious community, or with God (Pargament et al., 2005). For example, a mental illness may lead to feelings of anger toward, abandonment by, or being punished by God. In a survey of a national sample in the United States, McConnell et al. (2006) found that religious struggles were associated with a wide range of mental health symptomatology, including anxiety, depression, paranoid ideation, compulsiveness, and somatization. Although religious struggles may be triggered by psychiatric illness (i.e., secondary religious struggles), there is also evidence that religious struggles exacerbate mental health and physical health problems (i.e., primary religious struggles). Empirical studies of a variety of religious groups in a variety of contexts have tied religious struggles to declines in mood, quality of life, physical health, and even greater risk of mortality (Cummings and Pargament, 2010). Mohr (2013) elaborates on religious struggles and their consequences among Swiss patients with schizophrenia. These include feelings of religious alienation as a result of lack of support from patients' religious communities; a negative sense of self marked by feelings of guilt, despair, anger, fear, and suicidality; and vulnerability to the development of addictions in response to the sense of spiritual loss and emptiness.

Although there is little evidence that religiousness in and of itself generally causes delusions or hallucinations, people may express psychiatric illness through a religious idiom or filter (Greenberg and Witztum, 2001). Religious delusions occur in 36% of schizophrenic patients, 33% of bipolar patients, 17% of patients with substance-induced psychosis, and 26% of patients with other psychoses (Appelbaum et al., 1999). Some patients with religious delusions have committed self-harm, suicide, or homicide (Mohr and Pfeifer, 2009). However, the psychiatrist's task is complicated by the fact that hallucinations can be a normal part of religious experience in certain contexts, and are then experienced as positive. Nevertheless, hallucinations that scare, upset, or disrupt an individual's life are considered pathological. Pathological hallucinations are most often auditory, but can also be visual, tactile, olfactory, or gustatory (Mohr and Pfeifer, 2009).

Sims' (1992) three criteria help to differentiate between religious belief and religious delusion. (1) The experience reported by the patient gives the impression of a delusion rather than a mere religious belief. Both the observed behavior and subjective experience are in concordance with the psychiatric symptom. (2) The presence of other psychiatric symptoms such as hallucinations or mood or thought disorder make it more likely that the individual has a religious delusion rather than mere religious belief. (3) The outcome of the experience seems more in keeping with the natural history and course of a mental disorder rather than a life-enhancing experience.

Patients with Mental Illness Want Religiously Sensitive Care

Perhaps it should not be surprising that many patients would like to receive religiously sensitive healthcare, given the importance of religion as a resource and its significant implications for health and well-being. In one study, 83% indicated that their religious beliefs are closely tied to their state of mental and emotional health, and 75% said it is important to see professionals who integrate their values and beliefs into counseling (American Association of Pastoral Counselors Samaritan Institute Report, 2000). It is important to note that concerns about the openness of mental health professionals to religion and spirituality was the second most common reason for not seeking out help from this group; 15% said that they 'fear that (their) spiritual values and beliefs may not be respected and taken seriously.' African Americans and devout Evangelicals were particularly likely to voice these concerns. Other surveys of individuals

in the United States dealing with physical and emotional problems lead to the same conclusion – a majority of people would like to see religion and spirituality integrated into their treatment in a sensitive and respectful fashion (e.g., Lindgren and Coursey, 1995; Stanley et al., 2011). In spite of this expressed desire, religion is not often addressed in health care. Huguelet et al. (2006) reported that, although a majority of study patients with schizophrenia rated religion as important, only 36% discussed this issue with their clinicians.

In sum, there are a variety of sound empirically based reasons to justify a rapprochement between psychiatry and religion. In fact, over the past 75 years, theorists have made significant advances in conceptualizing the interplay between religion and mental health from a more balanced, nuanced perspective. These theoretical developments have led, in turn, to progress toward more spiritually sensitive psychiatric care.

Promising Theoretical Advances

Recently, two theoretical approaches have been advanced that hold particularly important implications for psychiatry: coping theory and attachment theory. Coping theory, derived from ego psychology (Lazarus and Folkman, 1984), emphasizes the role of religion in helping people understand and deal with major life stressors (Pargament, 1997). Religion provides individuals with coping resources (e.g., spiritual support from a sacred entity, religious reframing of suffering, confession) to assist them in coming to terms with life events, particularly those that reveal human finitude and frailty. In this sense, religion serves an empowering, ego-strengthening function. This may help to explain the high levels of religious involvement among people grappling with mental illness, as noted above. However, people vary according to the breadth and depth of their religious resources. Some are equipped with religious frameworks of meaning, ritual, and connectedness that allow them to withstand and even transform themselves in the face of significant stressors, including mental illness. Others have religious orientations that rest on a less benevolent view of the universe, other people, and the individual's place in the world; this group is more likely to experience profound religious struggles that compound the harsh impact of mental illness.

The effectiveness of coping from the perspective of this theory has to do not only with the individual's breadth and depth of coping resources, but also with the degree to which coping methods are well integrated with the demands of the situation, the needs and aspirations of the individual, and the larger social context. For example, active surrender of control to God's will has very different clinical implications for the individual who must take active steps to manage an emotional illness and the individual in hospice who has exhausted all treatment alternatives. The pursuit of religious growth and development can facilitate mental health and physical health more generally or interfere with those ends when it becomes overly scrupulous. Seeking out religious support for anxiety about gender identity will have different implications depending on whether the individual is part of a conservative or liberal religious tradition.

Attachment theory builds on the work of object relations theory and evolutionary theory. Attachment theorists have emphasized the role of religion in fostering a meaningful relationship between the self and the other (Granqvist et al., 2010). For most religious individuals, this attachment seeking involves a connectedness with a Divine other. People who pursue spirituality outside of traditional religious settings may seek a particular type of relationship with other entities or objects deemed sacred, such as nature, eminent figures, social justice, or work.

Several theorists have elaborated on this notion. Ana-Maria Rizutto emphasized the importance of learning about an individual's picture or image of God. She contends that this God image is heavily influenced by the internal representations of self and important others in the individual's relationship world, especially parents and subsequent key attachment figures (Rizzuto, 1979). Winnicott developed the notion of transitional objects as a key intermediary reflection of how a young child begins to translate experience with early attachment figures into predictions about others when engaging new individuals in the child's relational world (Winnicott, 1953). William Meissner extrapolated Winnicott's notion of the transitional object into his concept of creative illusion formation as a developmental capacity that plays an important positive and healthy role in the meaningfulness of religion participation (Meissner, 1984). Meissner described how growth-producing illusions were responses to objective reality that represented the person's capacity to transform (mere) reality into something reflective of inner significance and hope.

Consistent with this theory, emerging research has found a correspondence between the quality of an individual's parental attachments and attachments to God (Granqvist and Kirkpatrick, 2013). Thus secure attachments to parents are often tied to a secure felt connection to the Divine. Conversely, insecure attachments to parents are linked to anxious, avoidant, and ambivalent attachments to the Divine. There is also evidence that some people form a secure relationship with God in compensation for insecure relationships to parents, as in the case of religious conversions. These findings and the underlying theory on which they are based have important practical implications for psychiatry.

Promising Therapeutic Directions

Psychiatrists and other mental health professionals have begun to integrate greater religious and spiritual awareness and sensitivity into various treatment orientations (Pargament, 2007). Empirical evaluations of the effectiveness of these spiritually integrated treatments have shown encouraging results. Worthington et al. (2011) conducted a meta-analysis of 51 samples from 46 studies, and compared the outcomes of religious accommodative therapies and nonreligious therapies. They found that religious/spiritual psychotherapies (R/S) were as effective as secular psychotherapies with respect to the psychological

outcomes of patients. However, in comparison to secular psychotherapies, R/S therapies were tied to greater improvement among patients with respect to spiritual outcomes. They concluded that, for patients and contexts in which spiritual outcomes are highly valued, spiritually integrated therapies may be a treatment of choice.

Although a variety of spiritually integrated treatments have been developed, most have a cognitive-behavioral therapy orientation. These treatments have been applied to several patient populations, with promising results (Propst et al., 1992; Rosmarin et al., 2010; Harris et al., 2011; Hardman et al., 2003; Margolin et al., 2007, Richards et al., 2006). Even though much of the work on spiritually integrated treatments has grown out of a cognitive-behavioral orientation, practitioners from other therapeutic orientations have also begun to integrate greater spiritual sensitivity into their treatments. These treatment modalities have in common the attempt to provide a healthy revisiting of critical periods of development within the therapist–patient relationship. There is reason to believe that such experiences occur fairly often across healthcare disciplines. However, the impact of these 'sacred' or at least 'important' moments experienced in early development and brought into treatment awaits study (Lomax and Pargament, 2011).

New Directions

In recent years, great progress has been made in clarifying the interface between psychiatry and religion. Yet significant questions remain. First, because much of the work in this area has focused on western religion and medicine, it is important to extend research and practice to other cultures, particularly non-western contexts. Second, research in this arena is moving toward studies of more specific aspects of religiousness as they express themselves in specific forms of psychiatric illness (Hill and Pargament, 2003; Peteet et al., 2011). For example, it is important to consider whether mystical experiences and religious conversion contribute to destructive dissociation or positive integration among patients with significant mental illness. Similarly, research should explore the roles that patients' understandings of 'evil' and 'the Devil' play in their illness. There is some evidence that patients who try to make sense of their illness by invoking diabolical divine agents may be at risk for mental health problems and have increased risk of mortality (Pargament et al., 2001). The language of evil and the demonic may also offer a way to find meaning in otherwise meaningless suffering. Third, longitudinal studies are needed to disentangle the complex links between religion and psychopathology; in particular, the ways in which SMI may impact religious life and the ways religious problems and resources may foster or ameliorate psychopathology. Fourth, to foster more spiritually sensitive care and respond to the dearth of education about religious issues within psychiatric training programs, new models of psychiatric training must be developed and tested (Blass, 2007). Finally, further studies are needed to determine whether spiritually integrated treatments add to the effectiveness of psychiatric treatments. It is also important to learn how psychiatric treatments, including psychotropic medications, impact the spiritual lives of patients. These represent just a few of the many promising areas of study open to exploration by researchers in the twenty-first century.

Abstract

From the end of the nineteenth century, psychologists have had a keen interest in the empirical study of religion. Today, the psychology of religion is one among a family of social scientific approaches to the study of religion. Early interests in religious change through conversion and religious experience have continued in the contemporary psychology of religion, and new interests have emerged that have followed the trajectory of developments in broader psychology, including the relationship between religion and brain processes that are investigated through medical technology. The psychology of religion continues to bring into sharp relief issues in the study of religion, including methodological issues related to reductionism, quantitative vs qualitative approaches, and the relationship between the individual and the social environment, and also relates to broader interests in the formation and consequences of human beliefs and behavior.

The psychology of religion was a central part of psychology at its inception as an independent empirical discipline at the end of the nineteenth century. Psychology is also one of the families of human sciences that has made an important contribution to the study of religion. Argyle (2000) and Loewenthal (2000) provide accessible introductions. This presentation will look first at some key historical figures, then at contemporary research contributions, and finally at critical current issues. For an approach focusing on key figures in the history of psychology of religion see Wulff (1997).

History

Early work on the psychology of religion included quantitative methods, such as the questionnaire research of Edwin Starbuck on types of conversion. However, the most durable masterpiece of the early period was undoubtedly the qualitative research of William James. The psychology of religion continued to be a vigorous part of the discipline of psychology through the first quarter of the twentieth century, and the most widely read summation of that period was J.B. Pratt's *The Religious Consciousness* (see Wulff, 1997).

From about 1925, there followed a fallow period in the psychology of religion, in part reflecting the behaviorist direction taken by the discipline generally. However, with the growing emancipation of psychology that took place in the 1960s, there was a revival in the psychology of religion. This recent period has not seen as much development of major psychological theories of religion, indeed many would doubt whether they are appropriate. However, there has been a wealth of investigations in many aspects of religious experience and behavior.

William James

For his *Varieties of Religious Experience*, written at the turn of the century, James (1985) assembled a large quantity of autobiographical material about religious experience. Several of his conceptualizations of this material have become permanent contributions to the psychology of religion, such as his distinctions between 'once-born' and 'twice-born' conversion types, and between 'sick-soul' and 'healthy-soul' types. His description of mystical experience as having the hallmarks of ineffability, a noetic quality, transiency, and passivity has also stood the test of time.

However, James' approach has been criticized (e.g., Proudfoot, 1985) for his overemphasis on the private nature of religious experience as 'the feelings, acts, and experiences of individual men in their solitude.' Whereas James saw religious doctrines and church practices as arising out of individual experience, others have emphasized how much individual experiences are shaped by the religious tradition. These criticisms of James have been reinforced in recent years by the growing awareness of the extent to which experience is 'socially constructed.' There has also been concern about James' overreliance on vivid but unusual experiences and on the special phenomenological qualities of religious experience. Others would want to place the emphasis on how ordinary religious people interpret everyday events in religious terms, emphasizing that the hallmark of religious experience is not its unusual phenomenal quality, but simply the way in which a religious frame of interpretation is applied to experiences of an ordinary kind.

Sigmund Freud

Another rather separate strand in the psychology of religion that goes back to the early twentieth century is represented by the contribution of Freud, and the psychoanalytic tradition stemming from him. Freud published several books on religion, but his most enduring contribution has probably been *The Future of an Illusion* (1962), originally published in 1927. There, he argues that religion is a form of wish fulfillment (which is what he means by 'illusion'), and that God is a projection of the human mind. These were not altogether new ideas, and a similar line had been taken by Feuerbach. However, the fact that Freud formulated them in the context

of a well-articulated general theory of mental functions gave them a new authority.

Though Freud's views have been very influential, there has been a growing recognition that they are highly speculative and less authoritative than was initially supposed. It has also become clear that an alternative, more sympathetic view of religion can be developed within the framework of psychoanalytic theory, something that Freud conceded might be possible. A reconciliation between psychoanalysis and religion was begun by Freud's colleague Oskar Pfister, a Lutheran pastor. More recently it has been shaped by Winicott's concept of the 'transitional' world that was neither wholly internal nor external, but an illusionistic world that plays a constructive role in adaptation (see Meissner, 1984). Though Freud's own work on religion was surprisingly weak in case studies, others have now conducted rich case studies documenting the close parallelism that can often be found between relationships to parents and to God. Of course, this need not be interpreted as showing that God is nothing but a projection of the mind, just that concepts of God are often shaped by personal factors.

C.G. Jung

Jung took an unusual interest in religious symbols and doctrines. Indeed, one of the reasons for his break from Freud was that he was unhappy at what he saw as Freud's disparaging treatment of religion. Jung interpreted religious symbols in relation to the personal journey of 'individuation,' a journey from egocenteredness toward the 'Self,' involving the integration of the unconscious with the ego. Symbols are important both in representing the goal of this journey and also in facilitating it. Central to Jung's approach to religious symbols is his theory of the 'collective unconscious' and its archetypes; Jung does not regard religious symbols as just being features of the personal unconscious.

Jung had a strong interest in symbols of the Self, and saw God and Christ as being such symbols. However, he laments the extent to which religious symbols have now lost their psychological power and are no longer felt to be relevant to the journey of individuation. His work on Christianity included extended essays on the symbolism of the Trinity and the Mass (see Jung, 1969). He also took an extensive interest in Eastern religion, where he also found symbols of individuation, though he was opposed to Westerners taking up Eastern practices such as yoga.

Jung's view of religion is markedly more sympathetic than Freud's, though his reformulation of religion is at points decidedly heterodox. He tended to broaden religion to include anything 'numinous.' Also he emphasized that as a psychologist he could concern himself, not with religious metaphysics, but only with psychological realties (see Palmer, 1997). Though Jung saw 'God' and 'Christ' as psychic images and symbols of individuation, whether there was a 'metaphysical' God was something about which he had no official view. However, it would be a misreading of Jung to imagine that he thought people could work out their own salvation with the resources of the ego. He thought the ego was quite unable to secure 'individuation,' and emphasized the radical otherness of the 'Self,' of which God is a symbol.

The Contemporary Psychology of Religion

Much contemporary psychology of religion employs empirical research methods, and there follows a brief review of representative research findings. For a comprehensive guide to the empirical literature see Hood et al. (2009).

Individual Differences

The study of individual differences has long been an important part of the psychology of religion. The search for a particular kind of personality associated with religious allegiance has generally not been successful, largely because of the marked diversity of religious people. However, there is reliable evidence supporting an association between different personality types and different approaches to religion. This emerged first in connection with social prejudice, where 'intrinsic' religious people (those whose dominant motivation was religion) were found to be less prejudiced on average than extrinsically religious people (who might be involved in religion for more extraneous reasons). The same is true of committed vs consensual religious people (another set of terms for a related distinction). There has also recently been considerable interest in the relation of Jung's psychological typology, as measured by instruments such as the Myers–Briggs Indicator, to various aspects of religious life such as prayer and church leadership.

Mental Health

Mental health (at least as measured by self-report instruments) has been found to show the same relationship as social prejudice to types of religiousness, with intrinsic religious people having good mental health, but extrinsic religious people having relatively poor mental health. Even where religious people are not subdivided, religiousness tends to be associated with better than average scores on dimensions such as Eysenckian 'psychoticism.' When more objective measures are considered, religious people are often found to have lower levels of formal mental illness and abuse of drugs and alcohol. There is also growing evidence that religion has a positive relationship to ways of coping (see Pargament, 1997). There are probably a variety of explanations of the relationship between religion and health. These include 'selection' factors, such as alcoholics being less likely to go to church. However, there may be various ways in which religion can improve health and happiness, such as the therapeutic value of prayer, and the social support provided by the churches (see Loewenthal, 1995).

Developmental Psychology

Children's intellectual understanding of religion has been found to follow the usual path, documented by Piaget for many areas of cognitive development, from concrete to abstract modes of understanding. Early research showed that this applied to the interpretation of Bible stories, but the same general pattern seems to apply to other aspects of religious understanding, such as prayer and sacraments. There have been attempts to extend such 'stages of development' models to other aspects of religion, and to take them into adulthood.

The best-known work of this kind is Fowler's theory of 'faith development.' However, many critics have expressed caution about the proper limits of stage models of religious development. Stage models seem to work best for development in the intellectual understanding of religion, less well for other aspects; they also only seem to work better for religious development in children than in adults. The key issue is whether religiousness changes in a sufficiently predictable and universal way for the concept of development to be appropriate. It has been suggested that Fowler's 'stages' of faith development may be better seen as religious styles. There has been growing recognition that children's spiritual experience runs ahead of their ability to conceptualize it.

Religious Experience

There has been extensive empirical research on mystical and religious experience, though it is beset by the problem of how such experience should be defined. The initial question used in the research of Hay (1987) is characteristic: "Have you ever been aware of, or influenced by, a presence or power, whether you call it God or not, which is different from your everyday self?" Most empirical surveys find roughly a third of the population respond positively to such questions. Interestingly, the proportion is far from zero in atheists and agnostics. The experiences often occur at times of stress and generate feelings of peace and happiness. One of the most debated matters is whether there is a common core to such experiences that is independent of religious tradition and culture. Psychometric research by Hood suggests that there are two groups of descriptors, one focusing on the experience of unity, the other set of descriptors more influenced by religious background.

Attitudes

The measurement of religiousness is an aspect of the study of attitudes and involves the vexed question of the relationship between self-report and behavioral measures. It has been claimed by some that religious believing currently exceeds belonging. Though, on some measures, this appears to be the case, it depends on exactly what measures of each are used. One of the methodological principles to have emerged in the general literature on attitude measurement is that single-item measures of expressed attitudes are a poor predictor of behavior, whereas fuller self-report measures predict better, and there is reason to think that this applies to religious attitudes. Attitude change can be studied in relation to religious conversion.

Conversion

Conversion has long been a central topic in the psychology of religion. It is a multifaceted, and by no means uniform phenomenon. There are well-established differences between sudden and gradual conversion types, with the former being more conservative in religion and in other matters. It has also long been noticed that adolescence is the peak time for conversion, but the interpretation of this needs to take account of the fact that it is probably the peak time for apostasy as well. Conversion often does not represent as complete or permanent a change as is supposed. Also, many of those experiencing a conversion are returning to previously held attitudes; conversions among those with no previous religious affiliation are relatively rare. In recent years, there has been particular interest in conversions to new religious movements. In fact, these often seem to be associated with improvements in the sense of well-being. There is some evidence of mental health problems in those who leave new religious movements, though this by no means always occurs. There has been a growing interest in deconversion as a phenomenon that may parallel conversion.

Charismatic Religion: Speaking in Tongues

Speaking in tongues (glossolalia) is much the best-investigated charismatic phenomenon (Malony and Lovekin, 1985). Psycholinguistic research generally indicates that it is to be regarded as some kind of 'ecstatic utterance' rather than the use of an identifiable language. Social learning is apparently required before people are able to speak in tongues; this is suggested by the way in which people first watch it before joining in, and also get more proficient at it with practice. It has been suggested that it involves some kind of dissociated state of consciousness, perhaps a trance state or a regressive state, but there is as yet no clear support for such hypotheses. It has been difficult to identify personality characteristics of those who speak in tongues. This may perhaps be because it occurs in different ways in different settings, but there is as yet no generally accepted classification. However, there is some evidence that it is associated with positive personality changes, though it is not unique in having such beneficial effects.

Prayer and Meditation

There has been a growing interest in psychological perspectives on prayer (Spilka and Ladd, 2013). For example, aspects of prayer may provide for a kind of cognitive retraining; for example, thanksgiving seems to involve a change in the pattern of attributions people use. There is growing evidence that persistent prayer may result in altered patterns of experience. There has long been evidence that meditation alters people's levels of arousal, though probably not in any unique or distinctive way when compared to other procedures such as relaxation. However, meditation has notable benefits seen, for example, in emotional experience and reduced use of drugs and alcohol.

Perspectives from Evolution, Brain, and Cognitive Science

Alongside the kind of detailed approach to religious phenomena illustrated in the above section, a more general approach to the explanation of religion has emerged from cognitive science.

Cognitive Science

The cognitive science of religion (CSR) has multidisciplinary roots in cognitive psychology, evolutionary biology, neuroscience, and philosophy, and focuses on a variety of religious phenomena, including religious rituals, belief in gods and spirits, and the afterlife. The background assumption is that

religion is a predictable consequence of how normal cognition is structured and organized and is, in that sense, 'natural.' Though there is considerable diversity in CSR, the standard model focuses primarily on supernatural agents that, it is assumed, are overperceived in religion. Much CSR favors explanations in terms of specific mental devices. Some, such as Justin Barrett (Barrett, 2004), attribute perception of supernatural agents to a 'hypersensitive agency detection device' though, without independent evidence of such a device, it is questionable how far that provides an actual explanation. CSR sets out to explain 'religion' as an all-encompassing phenomenon in human history, whereas much current psychology of religion sees that as too broad and focuses instead on more specific phenomena.

Evolution

There has recently been much interest in the evolution of religion (Bulbulia, 2008). Most see religion as being a spin-off of other evolutionary developments, though there is a minority view that argues that religion has adaptive value. Most recent work on the evolution of religion takes a CSR perspective, though some argue that CSR is unnecessarily constrained in its assumptions and that a broader range of factors should be taken into account (Watts and Turner, 2014). Rather than looking for specific explanations of how religion evolved, it may be better to focus on the restructuring of cognitive capacities that led to the 'cultural explosion' of the Upper Palaeolithic period.

Brain

The study of the brain processes involved in religion promises to become a lively research area (Jeeves and Brown, 2009). There has been considerable interest in a possible link between the brain processes involved in religious experience and temporal lobe epilepsy. Though there are similarities in the two sets of experiences, there are also marked dissimilarities, and critics have pointed out that evidence that the same brain mechanisms are involved is weak (Jeeves, 1997). Some have suggested that the frontal lobes are equally important in religion, though more in belief and practice than in experience. Much recent evidence has focused on assessment of brain activity (assessed through fMRI scanning or in some other way) in religious practices such as meditation. Perhaps the most interesting conclusion so far is that there seem to be no regions devoted solely to religion. As evidence accumulates about the brain processes involved in religion, there is growing debate about whether or not they offer a complete explanation of religion.

General Issues

The psychology of religion involves a number of general issues about methodology and interpretation, including the following.

Relation to General Psychology

The psychology of religion currently lacks integrative conceptual frameworks and general theories. A psychology of religion that is no more than a fragmented study of various particular religious phenomena will never look impressive scientifically. The other pitfall to be avoided is, of course, offering a psychological theory of religion that is too simplistic to handle the relevant phenomena adequately. The kind of theory Freud offered, in terms of religion meeting psychological needs, proved neither convincing nor scientifically fruitful, and is not a good precedent to follow. However, the problems faced in studying religion psychologically are not unique. The study of emotion, for example, faces similar problems, in that emotion is as multifaceted a phenomenon as religion. Broadly conceived 'cognitive' approaches to religion may give useful coherence, as they are currently doing in the psychology of emotion. The psychology of religion interfaces with many other areas of general psychology. Indeed, it can be argued that the subject is pursued most fruitfully when its links with general psychology are strong.

Relation to Sociology

The separation between sociology and psychology is in some ways an artificial one, and affects the study of many social phenomena, including religion. Most religious phenomena have both social and psychological aspects. For example, conversion and speaking in tongues have been studied fruitfully from both perspectives. However, social and psychological studies often proceed in isolation from each other; it seems unlikely that either alone will be able to offer an adequate explanation of any religious phenomenon though there is a strong case for the psychology of religion having stronger links with the sociology of religion. This tends to raise the question of whether religion is to be understood in social or individualistic terms. Both perspectives are no doubt needed for an adequate understanding of religion, and the psychology of religion does not exclude a social approach. Though the increasing interest in the brain processes in religion are likely to pull the psychology of religion in a biological direction, the psychology of religion, like other aspects of psychology, will need to remain both a social and a biological science, and to hold together the different methodologies involved.

Relation to Theology and Religious Studies

Finally, what should the relationship be between the psychology of religion and theology? Different countries have different traditions about the relationship between theology and religious studies, some maintaining a sharp distinction between the 'insiders'' perspective of theology and the 'outsiders'' perspective of religious studies (including the psychology of religion); others have tried to maintain links between them. This issue is affected by the postmodern turn in philosophy, which is casting doubt on the possibility of any wholly detached, objective study of anything, including religion. The psychology of religion has been slow to accommodate itself to these general intellectual developments, though it is hard to see that it can stand aside from them indefinitely. One particular issue is whether there is scope for insiders' and outsiders' explanations to run alongside one another. Charismatic phenomena represent an example. It is not clear that the study of the psychological processes involved in charismatic religion excludes a complementary religious account in terms of the activity of the Holy Spirit.

The Nature of Explanation: Beyond Reductionism

Many of these issues are brought together in questions about the nature of explanation in the psychology of religion. Explanations in psychology are seldom complete explanations, and are certainly unlikely to be such in the psychology of religion. This means that religion will not be reduced to psychology, or 'explained away.' Equally, religion is not a 'natural kind,' and all explanations in the psychology of religion will therefore be culturally and historically bound and depend on interpretations of the nature of religion; the psychology of religion can never hope to provide a science of religion that is a 'view from nowhere.' Nevertheless, there is no sharp boundary between the explanation and interpretation of religion, and it is inherent in the nature of religion that it will adopt a reflexive approach.

Abstract

The sociology of religion is a branch of social science that aims to describe and explain religion in society through empirical investigation and testable theory. It is concerned with individual beliefs and behavior on the one hand and norms and institutions on the other, and with their reciprocal influences. Sociologists seek to explain how religion is affected by social forces and how religion affects other domains in society.

Introduction

Disciplinary Boundaries

Sociology is concerned with the way that people organize themselves in groups, how those groups influence individual beliefs and behavior, and how different kinds of collectives interact in a society. Some of these groups are defined by their attention to gods or things that are sacred and so are of particular interest to sociologists of religion.

The sociology of religion is a social science; unlike theology or the philosophy of religion, it does not seek to evaluate doctrines, arguments, practices, or ways of life. Nor is it concerned with the history, scriptures, and comparative nature of different religions, as the discipline of religious studies would be, except to the extent that these features are relevant to sociological questions. Instead, it sets out to describe and explain religion in society through empirical investigation and testable theory (Aldridge, 2013; Beckford and Demerath, 2007; Clarke, 2009; Emerson et al., 2010; Fenn, 2000; Roberts and Yamane, 2011; Turner, 2010).

The boundaries between different aspects of the scientific study of religion are not always clear. Political scientists are typically concerned with the influence of religion on political choices, institutions, or practices; geographers may be interested in the spatial distribution of religion. The economics of religion is a relatively new subdiscipline that generally involves the application of rational choice theory to religious phenomena; the metaphor of a market for religion has been widely adopted. Anthropologists are demarcated from sociologists more by method (for example, ethnography) than by subject matter, although in the past they were usually concerned with traditional, non-Western societies. Psychologists are typically interested in individual personality, emotional needs and responses, and cognition, and hence explanations tend to be at the individual level. By contrast, sociologists are more concerned with how social factors affect religious attitudes and behaviors (and vice versa).

Defining Religion

Describing the sociology of religion requires knowing what one means by religion as well as sociology. Religion can be characterized in terms of what it is (substantive definitions) or what it does (functional definitions). Substantive definitions are generally easy to grasp; religion involves beliefs, practices, or institutions that are based on gods or supernatural forces. The difficulty is that not everyone will agree on what is 'supernatural.' and moreover some groups (for example, some intellectual varieties of Confucianism or Buddhism) seem religious without relying on the supernatural. Functional definitions sidestep these problems by stipulating that religion provides meaning, promotes social cohesion, or performs other functions for adherents and society. Almost inevitably, however, some groups or ideologies that few people regard as religious fulfill the same functions. Interesting questions about the extent to which environmentalism, for example, resembles religion then become uninteresting ones about whether the movement really is a religion. In practice, the difficulties around substantive definitions are minor; it may not be possible to set out necessary and sufficient conditions for something to count as a religion, but family resemblances enable us to identify members of the class.

Scholars wrestle with a number of related concepts that are distinct from religion, in particular magic, spirituality, the sacred, and the secular. A good deal of attention has been devoted to the cultural specificity of these terms. Ultimately what matters is utility: one wants to understand each concept, argue about what is important, and use vocabulary that is suited to the task.

The Founders

Religion was a central preoccupation of the founders of sociology, in particular Emile Durkheim (1858–1917) and Max Weber (1864–1920). It also received attention from Georg Simmel (1858–1918) and to a lesser degree Karl Marx (1818–83). The influence of the sociological classics has been large and enduring, arguably to an unhealthy degree. The humanities are in continuous conversation with the past, while science quickly leaves its past behind; the sociology of religion sometimes seems more akin to the former than the latter.

One of the reasons that Durkheim and Weber are so often cited in this context is that they jointly cover religion's role in society. Durkheim stressed its function as social glue; for Weber it could act as social solvent. As the complementary ideas of social cohesion and cultural transformation persistently arise in writing about religion and society, it is natural for scholars to genuflect in the direction of the classics.

Key Debates

The Social or Evolutionary Basis of Religion

Sociologists treat religion as a social phenomenon. For early social scientists, the innovation was to treat it as a human rather than a divine creation. For contemporary sociologists, the challenge comes from a Darwinian direction, via nature–nurture debates. Are humans naturally religious, and if so, why? Is there a hereditary predisposition to be religious?

Evolutionary psychologists and cognitive scientists have offered a number of theories to explain the existence of belief in supernatural entities, the creation of ritual systems, and other features of religion. Some suggest that religion provides direct benefits to individuals and groups in adapting to their environment – for example, in promoting cooperation – and so will be favored by natural selection. Others doubt that religion itself is adaptive, but view it as a by-product of other dispositions that do increase the chances of survival. People may come to believe in the existence of supernatural agents, for example, as a result of developing the capacity to trace effects to their causes, or to recognize the intentions of other beings (Bulbulia et al., 2008).

If demand for religion is universal, then cross-national differences in religious involvement must be explained by variations in supply; this idea is one of the foundations of the market model of religion, at least in its dominant supply-side version. It is clear, however, that many people now have no interest in religion, and it does not seem axiomatic that religion is a necessary feature of life for individuals or societies.

Secularization

Sociology of religion came into being with the question of how modernization affects religion. At the level of social institutions, the answer is clear: religion loses power and authority. The term 'differentiation' describes the separation of government, law, education, medicine, and other realms of life from the control of religious organizations. What remains disputable is the impact on individual self-identification, belief, and practice. Proponents of the secularization thesis assert that various aspects of modern life tend to bring about a decline in the prestige and popularity, as well as the power, of religion (Bruce, 2011); they point to the clear inverse relationship between socioeconomic development and religious involvement. Opponents cite the United States as a counterexample and the persistent religiosity of societies that are now modernizing (Stark and Finke, 2000).

Although the debate is frequently depicted in black and white, much of the recent research uses various shades of gray. It is commonly conceded that traditional religious organizations and orthodoxies are struggling, but many scholars claim that religion is being transformed rather than eroded. Belief and practice, in their view, are individualized, possibly privatized, but still with us. For secularization theorists, the issue is whether these new, less formal belief systems have the personal and social significance that characterized old-time religion.

Fundamentalism and the Persistence of Conservative Religion

As modernization began to undermine support for traditional beliefs, some religious leaders reacted by defending what they regarded as core principles. This movement became known as fundamentalism, using the label adopted around the turn of the twentieth century by American Protestant theologians who sought to identify the fundamental tenets of the Christian faith. Its contemporary common usage tends to be pejorative, particularly as fundamentalists from different religions (Hindu, Jewish, and Muslim as well as Christian) have become active in politics. For many sociologists of religion, however, 'fundamentalism' remains a useful technical term to refer to an important strand of doctrinal conservatism, typically involving literal interpretation of scripture and adherence to traditional values.

The importance of fundamentalism demonstrates the complexity of social change; however strong the current, not everyone is carried in the same direction. Understanding the impact of modernization involves studying reactions against it as well as forms of adjustment to it (Marty and Appleby, 2004).

Sects and New Religious Movements

The history of religion, like the history of thought, is marked by a flowering of creative energy in particular times and places. The Reformation brought a proliferation of new religious groups, some of which established themselves as powerful national churches while others remained resolutely outside the mainstream. The late nineteenth century in the United States was a fertile time for sects, groups in tension with society that claimed to be in unique possession of the truth. The 1960s, 1970s, and 1980s saw a considerable rise in interest in – and also concern about – a variety of 'cults' (a term that can be used in a technical as well as an unflattering sense), some with roots in Hinduism and Buddhism, others in evangelical Christianity, and yet others (like Scientology) that were completely new creations. New religious movements (NRMs) is a generic descriptor of sects and cults (Hammer and Rothstein, 2012).

Innovation is an important topic in sociology, and religion experiences flux as well as persistence. The study of NRMs is, in part, an investigation of how, when, and where society changes. The challenge for researchers in this field is to move from the particular (and many groups have been described in fascinating ethnographic detail) to the general. One needs to know not just how NRMs fit into the story of religious change in the modern world, but also what they tell us about the culture generally. Because the number of people involved is relatively small, 'very little' is a possible answer.

Alternative Spirituality

The diverse currents of belief and practice previously described as 'New Age' and now more often known as 'alternative spirituality' attracted increasing attention from sociologists of religion in the latter part of the twentieth century. Some suggested that this belief system was so well adapted to contemporary conditions that it would displace conventional, institutional religion. Certainly, the focus on the self as a trinity of mind, body, and spirit was particularly attractive to Western

individualists, especially when an ideology of oneness with nature, humanity, or the universe helped to leaven the appearance of solipsism (Lynch, 2007). Alternative spirituality has, however, followed the pattern seen for NRMs, important to a small minority and ridiculed or ignored by most.

The extraordinary variety of ideas that fall under this heading points to a key problem for nonorganized religion. Individuals may want to pick and choose their beliefs, but if the list of options is very long, it becomes hard to identify with any common cause.

International Migration and Religious Diversity

Apart from secularization, the major source of religious change in developed countries has been immigration. The religious landscapes in North America, Europe, and Australia have been transformed by the arrival of millions of people of different religions (Eck, 1997). The growing number of Muslims in Western Europe has been a particularly important development (Open Society Institute, 2010). Religion is coming to be seen as a key social division, and the social scientific study of religion, ethnicity, and migration now overlap. Public concerns about social cohesion and political violence rooted in religious difference have helped to bring the study of religion back from the margins of scholarly research.

Theory and Methods

Levels of Analysis and what Is to be Explained

By its nature, sociology is concerned with relationships between individuals, groups, and society as a whole. Analysis may focus on one of these levels or how they are linked. At one extreme, there are macrosocial theories of church–state relations, or the differentiation of law, medicine, education, and other institutions from religion; at the other, there is microsocial research on conversion, religious practice, and so on. At an intermediate level, one finds studies of religious organizations, for example, charismatic leadership or congregational dynamics.

Religion can be affected by other social forces, and it can itself affect individuals and society. For sociologists, then, religious participation may be what is to be explained or what does the explaining. For quantitative researchers, religious involvement may be the dependent or the independent variable.

As suggested above, especially in relation to debates over secularization, a principal preoccupation of sociologists of religion has been to explain the relative prevalence of religion or religious commitment in different times and places. Many of the main theories of religion aim to account for the success or failure of the religious enterprise in relation to other factors. Researchers study continuity and change; religious growth and decline; the connection between believing and belonging; nontraditional spirituality; the influence of age, gender, and socioeconomic characteristics; intergenerational transmission; cross-national comparisons; and much else besides.

There is much more to the sociology of religion than research on variations of religious commitment. Social scientists are more often concerned with the impact of religion on other aspects of life. In these studies, religion is treated as an explanatory variable. As discussed in more detail below, religion can affect anything from health to family size to trust and tolerance.

Religion versus Religiosity

Measurement of religion in a narrow sense would be simply a matter of recording affiliation (as Catholic or Buddhist, for example). For some people, however, affiliation is purely nominal; others will have a serious personal commitment, seeing faith as important in their lives. What matters may be not only or even mainly one's notional identity or affiliation, but instead one's degree of religious commitment, or 'religiosity.' Religiosity is bound up with attitudes, behavior, and values, while religion per se is arguably more like ethnicity, something that for most people is transmitted to them rather than being chosen by them.

There is no single marker of having a religion or of being religious. A number of factors may be relevant: belief, practice, membership, affiliation, ritual initiation, doctrinal knowledge, cultural affinity, moral sense, core values, external perception, or something else. 'Having a religion' is an ambiguous notion, and 'being religious' is even more difficult to define or observe.

In recent years, it has become conventional to focus on three aspects of religious involvement: belief, practice, and affiliation. The first two dimensions seem fundamental, representing the distinction between the internal (belief in creeds, knowledge and acceptance of doctrine, affective connection) and the behavioral (participation in services, private devotion, and communal activity).

Methods and Scope

The sociology of religion, like the wider discipline, tends to be divided as much by method as by topic. Some researchers specialize in the quantitative analysis of large data sets from social surveys; others use qualitative methods such as personal interviews or participant observation. Although some research projects combine the two, a degree of mutual suspicion is common. Qualitative researchers tend to regard questions with precoded responses as superficial and the statistical analysis of data as inaccessible; survey researchers often see limited interest in small-scale studies producing findings that cannot be generalized.

Survey research on religion is generally concerned with individual faith and practice. The analysis aims to identify the effects of particular factors, controlling for potentially confounding variables. Some studies use aggregate data (for example, the total number of church weddings in a particular year or the breakdown of the Muslim population by ethnicity). Work on religion is being influenced by growth in data processing power and the development of increasingly sophisticated statistical techniques.

Although the sociology of religion has its origins in the West, its current scope is international and cross-cultural. While its concerns are dominated by the role of religion in contemporary developed societies (leaving historians and anthropologists to work on the past and traditional religion), the

discipline does not confine itself to any place or period. Although a large proportion of the research effort has focused on the United States, reflecting the American preponderance in the field, public interest in Eastern spirituality, Islam, the Pentecostal movement, fundamentalism and political extremism, and other transnational issues has encouraged a broadening of geographical scope.

How Religion Is Supplied

Types of Religious Organizations

It is common for sociologists to divide religious organizations into four types: churches, sects, denominations, and cults. Although the terms are Christian, the typology can be applied in other cultural contexts. A church (or within any particular society, the Church) represents the dominant religious tradition; its authority often extends beyond the religious sphere. The sect is more fervent and reforming; it may also claim to hold a monopoly on religious truth, but only a fraction of the population is prepared to recognize those claims. As sects become more worldly and churches are obliged to accommodate the existence of religious competition, they become denominations, mainstream groups that comfortably coexist. Finally, the cult has little respect for religious tradition, and in turn receives little respect from outsiders. The strength of the societal reaction to cults is such that the term itself is pejorative in common use, and sociologists of religion tend to refer instead to 'NRMs.'

This typology may lose its utility as people become less deferential toward religious groups and less concerned about the differences between them. Claims to unique legitimacy are viewed with derision in modern pluralistic societies, and increasing tolerance in conjunction with decreasing orthodoxy means that sects and cults are no longer regarded as especially deviant. All religious groups hover in status between the old categories of denomination and cult, receiving respect or disrespect according to circumstances.

Local Religious Organizations

The organization of religious involvement varies across groups and between societies. The idea of a relatively stable worshipping community that meets for religious services is characteristic of the main monotheistic religions (Judaism, Christianity, and Islam). Activity in other religious traditions is often organized differently, with individuals making visits to shrines or temples at irregular times, on special occasions, or for festivals. The tendency of Hindus, Buddhists, and other non-Christian immigrants in Western countries to develop congregations and national denominational bodies is of considerable interest to sociologists of religion.

Many Christian denominations are organized hierarchically, with local churches grouped into districts (dioceses, circuits, etc.), which in turn report to a provincial or national leadership. The degree of centralized authority may be high or low. Complete localism is achieved by independent or congregational churches that are entirely self-governing. Some 'house churches' eschew the conventional form completely, in that collective worship does not depend on having a dedicated space or direction from religious professionals.

Large, so-called megachurches have become an important part of the Western religious landscape. Many have been created by – and are dependent on – the charismatic efforts of a founding leader. Some set out to bring in 'seekers,' people who are unenthusiastic about conventional churches but hope to find a group or idea that will meet their needs (Thumma and Travis, 2007). The size of the megachurch makes it possible to provide high-quality services, both in terms of religious and secular content.

Religious Specialists

Sociologists study the way that institutions act through people, and the human face of religion is often that of the prophet or priest. These specialist roles depend on some combination of personal charisma and official authority. Even where clergy are in a sense religious functionaries, employed largely to conduct rituals for local congregations, their success may be dependent on individual qualities. Conversely the prophet, shaman, or magician must quickly acquire some kind of public standing or risk being treated as a madman.

While there is a considerable amount of cultural and religious specificity in the deployment of religious specialists, a number of roles are found widely. The prophet/entrepreneur has new ideas to promote, either within an existing tradition or completely outside of them. The evangelist seeks to spread a recognized form of belief or practice. Clergy are responsible for dispensing services on behalf of a religious institution; magicians and shaman are less able to call on external sources of authority, although they may operate within a well-understood system of practice. An intriguingly general type is the monk, nun, or theological scholar, a religious professional who to a greater or lesser extent is separated from ordinary social life.

Ritual and Religious Activity

The nature and timing of religious activity shows both continuity and change. On the one hand, rites of passage (ceremonies marking key life events such as birth, coming of age, marriage, and death) have clearly existed for millennia and continue to be important elements of religious practice. On the other hand, daily or weekly observance might once have been left to religious professionals, but now one sees routine acts of worship involving the community of followers.

Ritual may be highly formalized, with set texts (liturgies) and special clothing for the clergy, but it can also be informal and even spontaneous to some degree. Much religious practice is individual (for example, private prayer) rather than collective, however. The debates over 'alternative spirituality' partly relate to whether the balance is shifting in the direction of privatized activity as well as belief.

Religion and the Media

Since the invention of the printing press, new forms of communication have been used to disseminate religious teaching. Religious broadcasting on radio and television is

a staple in many countries, some of which explicitly require broadcasting companies to devote air time to religion.

The relaxation of regulation in the United States led to the 'televangelism' phenomenon, with a number of conservative Protestant pastors leading the way. It is an empirical question whether such broadcasting attracts new participants, draws the faithful (or their financial giving) away from conventional churches, or merely supplements the religious involvement of churchgoers. There is little evidence that television has revitalized religion in the West, but it has helped to launch some religious leaders into politics.

The Internet offers new opportunities for religious organizations, entrepreneurs, and evangelists. It also produces new threats, by making critical information and commentaries readily available, by showcasing the sheer diversity of possible worldviews, and by providing access to myriad alternative uses of time and attention. It remains to be seen how well religion responds to these challenges.

How Religion Is Consumed

Religion and the Life Course

Whether or not humans are inclined by nature to be religious, it is clearly the case that taste for religion is cultivated within families and the social environment. If one wants to predict someone's religion and religiosity, two pieces of information will take one most of the way: where the person grew up and how religious his or her parents were. The amount of effort parents invest in the religious socialization of their children is strongly associated with the importance they themselves attach to the religion.

As children emerge into adulthood, they may diverge from the family path; in the Western world, the motor of declining affiliation and attendance has been a drift away from religion at this point. Within any given generation, the average level of religiosity appears to be fairly stable over the life course; contrary to common belief, there is little evidence that people become markedly more religious with age. Exceptions are most likely to occur as a result of family formation, when people use their own upbringing as a model for how children should be raised.

Gender Roles

It is well known that women tend to be more religious than men by virtually any of the measures commonly used. The only exception is found in particular groups (for example, Orthodox Jews) where the responsibility for public practice falls on men.

Sociologists typically reject the idea that differences between men and women in religious belief and behavior are largely determined by biology. Boys and girls have traditionally been socialized to be different; girls are trained to be more submissive and compliant, and accordingly are more likely to embrace or at least fail to reject religion. Differential socialization also affects education, labor market participation, and caring choices, which in turn affect religious behavior.

Religion may serve particular functions for women because of their social location. The conservative ethos of religious organizations validates and reinforces the choice to be a homemaker, and the 'love and compassion' narrative of many religions provides meaning and psychological support to those tasked with caring. To the extent that mothers are responsible for the moral socialization of their children, they may find that religious concepts, private observance, and attendance at services assist them in that task.

Ethnicity, Nationalism, and Religion

Religion and tribal identity were bound up in traditional societies, and they remain closely connected in many modern ones. Although the rise of 'universal religions' such as Christianity, Islam, and Buddhism helped to separate the concepts of religion and ethnicity, the separation is far from complete. It is now common for sociologists to discuss 'ethnoreligious groups' (rather than 'race,' for example) as related forms of social identity and potential social division. And because many churches or mosques are associated with specific immigrant groups, scholars studying religion are interested in ethnicity.

Religion continues to be pressed into service in support of nationalism. It helps to define the boundary between one group and another, and ironically appears to be more 'rational' for these purposes than characteristics such as language, race, or customs. The honorary kinship between believers helps to create the 'imagined community' of the nation. The influence runs both ways; a demand for national or ethnic self-defense helps to encourage religious participation, where religion serves as an identity marker.

Mysticism and Religious Experience

Not all religion is organized. In addition to mundane private religiosity, some people have religious or spiritual experiences that are out of the ordinary. The nature of these experiences can be highly varied, and include visions of the divine, mystical enlightenment, extraordinary feelings of contact with a different reality, and so on. These sensations may be consciously sought or unexpected, and welcomed or rejected by institutional religion.

Although most research on this topic has been undertaken by psychologists rather than sociologists, the character and incidence of these experiences are historically contingent and socially patterned. One might even suggest that such apparently spontaneous and subjectively interpreted experiences amount to learned behavior, with the culture providing the repertoire. Different religious traditions encourage different kinds of visions or insights, and the individualism of the modern age is conducive to everything from 'born again' to Buddha-like enlightenment.

Conversion, Switching, Apostasy

As societies have become more religiously diverse, the number of people changing their religious affiliations has tended to increase. The changes may be from one world religion to another or from one denomination to another; these moves are often known as 'conversion' and 'switching' (or 'reaffiliation') respectively, but the terminology can vary. The growing acceptability of having no religious affiliation means that changes into and out of religion are also important.

Sociologists are interested in when, why, and among whom such changes occur. Marriage is often the occasion, as spouses seek to avoid the problems that different religious identities, beliefs, and practices might produce, not least in raising children. Geographical moves may encourage leaving, joining, or switching. The strictness or distinctiveness of the religion of origin has received considerable attention as a possible inhibitor of religious mobility.

The impact of religious diversity on religious involvement remains an open question. Are people more religious when a single church is dominant and defines a taken-for-granted worldview, or are they more likely to participate when numerous alternative churches are available, each working hard to gain adherents?

Religion/Religiosity as Explanatory Factors

As well as being interested in religion for its own sake, sociologists are concerned with the impact of religion on other aspects of life – what are often referred to as 'outcomes.' Religion can affect health, drug and alcohol use, crime and deviance, fertility, mortality, marital stability, social and political attitudes, morality and altruism, tolerance, voting, civic participation, trust and social capital, education, economic activity, happiness, and any number of other areas.

By far the largest literature is in health, where there are journals specifically dedicated to work in this field and thousands of articles have been published (Koenig et al., 2012). The evidence suggests that the positive effects of religion (e.g., on lifestyle, emotional stability, and in social support) dominate the potential negative ones (anxiety, fatalism, etc.), but the balance will depend on the particular case.

There is a strong association between homogamy (marriage within the same group) of all kinds and marital stability: the more similar spouses are in religion (but also in age, ethnicity, education, social class, and so on), the more likely they are to stay married. A further issue is whether some religions are better for marriage than others (or none). The answer is probably affirmative – the theology and communal structures of some groups strongly discourage separation and divorce – although selection bias may also be relevant (if, for example, people with no religion tend to be less traditional and more susceptible to partner change than others).

The influence of religion on fertility has been a standard topic in demography, for example, on its historical role in the European fertility transition, the changing importance of 'Catholic' fertility, or its contemporary significance in less developed countries. Specifically religious norms may matter little unless the religious institutions supporting them play a significant role in the lives of their members.

Religious affiliation may be associated with socioeconomic position for many reasons, including not only group values but also historical advantage, social networks, and preferential treatment. Education is an important determinant of economic success, and educational attainment has historically been associated with religion. An important influence of religion on socioeconomic status may be a protective one relating to religiosity rather than affiliation. There is a substantial literature on the inverse association between religious involvement and criminal activity, drug abuse, and a range of risky or antisocial behavior.

Religious beliefs are likely to influence other social attitudes. In previous decades, it was commonplace for political parties in continental European countries to be associated with particular religious groups (or alternatively to appeal to the self-consciously secular), but these links are rapidly disappearing. Religiosity has become one of the best predictors of voting intentions in the United States, however.

Religion and Public Policy

Religion intersects public policy in a number of areas: church establishment and state regulation of religion; faith-based initiatives; official protection of religious belief, for example, through laws on blasphemy, or protection against discrimination; laws on incitement to religious hatred; the accommodation of religious differences in education and employment; criminal justice; housing and urban planning; immigration; and health care and social services.

Religious groups are major providers of social services, and government-backed 'faith-based initiatives' support such roles. Church action may be direct (for example, in providing sheltered accommodation and hospice care) or indirect (for example, in promoting charitable giving, voluntary service and informal networks of care). Common issues concern the extent to which publicly funded groups engage in religious activity and whether such groups deny their facilities to people of whom they disapprove.

Protection of religious beliefs (in particular through legal prohibition of blasphemy) has tended to be replaced by protection of persons (by outlawing incitement to religious hatred). Freedom of belief is protected by legal barriers to discrimination based on religious or nonreligious views. Conflicts arise when religious individuals claim the right to discriminate against others, with gender and sexuality being the usual grounds.

Religion enters into a number of debates over public regulation of education. Church-run schools – in many instances state-supported – exist in virtually all countries, but the arrival of religious minority groups seeking their own schools has led to fears that separate education will increase social segregation. Pressures from religious minorities may also promote the existence of single-sex schools or increase the cultural sensitivity of some aspects of the curriculum in areas as disparate as art, biology, sport, and of course religion itself. Conflicting pressure groups in Western countries attempt to make state-funded education more or alternatively less Christian. The general issue of accommodating the religious requirements of minority students (for example, for prayer facilities or special holidays) is one that schools share with employers. Finally, dress codes in school have been highly contentious, particularly in France (where years of debate culminated in an outright ban on head scarves and other overt symbols of faith in state schools) and also elsewhere.

Religion can be a sensitive issue in the workplace; issues include equal opportunity in recruitment, work schedules, food supplied on site, holidays, uniforms or dress codes, social activities that tend to exclude some employees (for example,

because they do not drink alcohol), provision of prayer rooms, and offensive behavior directed at members of certain groups. A great deal of attention has been given to providing 'reasonable accommodation' of religious requirements.

Religion affects policy and practice in the areas of policing and criminal justice. Security profiling is by design a form of discrimination, and members of religious minorities (especially Muslims) are disproportionately likely to be identified as suspect. Similarly, police stop-and-search activities have created a good deal of ill feeling. Prejudice or intergroup conflict can lead to the commission of hate crimes against people from particular religions. In prisons, there are religious issues concerning food, chaplaincy, and abusive behavior.

Immigration policies sometimes show favoritism toward people who share the country's dominant religion. Conversely, it can be difficult to obtain visas for minority religious leaders. Authorities may treat arranged marriages unfavorably, which tends to affect particular minority groups.

Housing policies that relate to extended families can have a disproportionate impact on some religious groups. Urban planning problems are generally related to equal treatment of minority applications (for example, permission to build temples and mosques in historically Christian countries, or churches in Muslim ones). A considerable amount of symbolism is involved in marking space with public buildings, particularly ones that seem large and exclusive. There are also issues of fairness; church bells are commonly accepted in European countries, but amplification of the Muslim call to prayer is much more likely to be restricted.

A host of cultural issues with religious roots are significant for providers of health and social services. Some medicines, procedures, or immunizations are not favored by certain religious groups; mixed wards may not be acceptable to everyone; hospitals must accommodate a variety of dietary restrictions; hospital chaplains need to serve diverse groups; postmortem requirements are variable. Similar issues arise in residential care. The take-up of contraceptive and some screening services may vary by religion, and how or by whom female patients are treated is occasionally an issue. Whether religiously motivated circumcision should be performed is also debated. The religion (as well as the race) of prospective adoptive parents has provoked discussion. Members of NRMs or neopagan groups complain that they are sometimes the target of unjustified child protection orders.

Groups concerned with animal welfare have objected to methods used by kosher and halal butchers (who slaughter animals without first stunning them). Jewish and Muslim organizations have protested that their methods of slaughter are humane, and the governments have typically resisted imposing restrictions. Pressures from religious and animal welfare groups will not be easy to reconcile, however, and it seems unlikely that the issue can be settled definitively.

Abstarct

This article will present an overview of the main religious forms in East Asia (China, Taiwan, Korea, and Japan). It will outline the main religious traditions, dealing both with organized and established traditions such as Buddhism, Taoism, Confucianism, Shinto, and the New Religions of the region, as well as the amorphous but influential folk religious traditions that form the bedrock to all religious activity in the region. Attention will be paid within this wider folk tradition to beliefs and practices relating to shamanism and to the role of charismatic figures, healing, and millennialism. Issues such as the relationship of religion and nationalism (especially critical in Japan in relation to Shinto) and the integrative functions of religion in East Asia will be discussed, while consideration will be given to new religious movements, especially Japan, as manifestations of a religious response to modernity and as a product of the tense interactions between modern change and adherence to cultural traditions and beliefs. In addition, reference will be made to the scholarship produced within the region, and the significance this has for the wider field of the social sciences.

Comprising China, the Korean peninsula, Taiwan, and Japan and containing a sizeable proportion of the world's population and home to some of the oldest and most advanced cultural systems in the world, East Asia has produced a number of major religious traditions such as Taoism, Confucianism, and Shinto, as well as developing its own distinctive regional forms of Buddhism. Besides these religions there exists also a pervasive folk religious tradition linked to customs, practices, and beliefs that forms the underlying bedrock to the entire religious structure of the region. Especially since the nineteenth century, too, numerous new religious movements have developed in the region, in response to rapid social change and modernity, but often reasserting many of the themes of folk religion and of the traditional religious environment within new forms adapted to the modern age. The region has also developed its own scholastic traditions which are essential for any understanding of its religious dynamics and that provide important new perspectives and alternative voices from those derived from Western academia.

East Asia in Religious Contexts: an Overview

East Asia represents a problematic area of analysis because of its size, vast and varied population, historical and social complexity, the differing historical and social experiences of each country, and its multiplicity of religious forms. This, and the existence of religious expressions associated with particular countries of the region, raises questions about how far one can talk about the region as a whole in religious or cultural terms. An example here would be Shinto, which is specific to the Japanese cultural sphere and which raises questions about the use of religious ideology in the formation of nation states, about cultural identity, and about the relationship between religion and politics. However, while Shinto provides meaningful examples relating to such questions, it cannot necessarily be considered as an exemplar of the patterns of East Asian religion in general, given that no similarly identifiable national religious traditions exist in other countries in the region. Similarly, the religious responses to rapid social change and modernity, which have seen the formation of new religious movements in different parts of the region, cannot necessarily be considered as indicative of a region-wide commonality. Many of the new movements that have arisen in Korea, e.g., draw heavily on evangelical Christian themes as well as the shamanic beliefs and practices which are central to the Korean tradition, while Japanese new religions have drawn much more heavily on Japanese cultural traditions based on Buddhism, Shinto, and folk religion. Indeed, scholars from the region have been reluctant to draw many parallels between the countries of East Asia. Japanese scholars, e.g., prefer to discuss the Japanese new religions in the comparative context of new religions in the West rather than in the Asian context. Rather than expressing similarities and commonalities, indeed, the academic traditions of each country in the region tend to emphasize concepts of cultural uniqueness and difference and where they have sought a comparative focus have looked outside the region.

Religious Traditions of East Asia: Buddhism, Confucianism, Taoism

The East Asian religious spectrum includes historical religions that have influenced the whole region and localized traditions that are influential in some, or one, area but that cannot claim cross-border significance. Three major historical traditions have been influential across boundaries and formed part of the religious constitution of the region as a whole: Buddhism, which although coming from outside, has taken on particular regional characteristics in China, Korea, Taiwan, and Japan, and Taoism and Confucianism, both of which originated in China but have also been influential in Korea, Taiwan, and Japan.

Buddhism

Buddhism entered East Asia along the major trade routes, supported by the patronage of ruling elites who saw it as a means of strengthening the ethos and power of the state. This was particularly so in Japan, where it was adopted as an arm

and pillar of the state from the seventh century onwards. While its growth and development of an extensive monastic system owed much to its promises, expressed in popular Buddhist texts such as the Lotus Sutra, of spiritual emancipation for all, and while it has developed monastic forms and meditative traditions (most famously Zen in Japan) with a primary orientation towards renunciation and spiritual transcendence, Buddhism's main orientation in East Asia has been social, familial, and mundane. As elsewhere, it has used magical symbols and rituals for the amelioration of the living, both individually and in social contexts, and operated as a religion dealing with death and the after-life, offering an eschatological framework of other-worldly salvation through a range of memorial and funerary services which aid the dead spirits in their journey to the other world. It has been through Buddhism that the spirits of the dead have been transformed into ancestors who guard over their living kin and in this way it offers solace to the bereaved while reinforcing the solidarity and continuity of the household.

Confucianism

While the thoughts of Confucius (551–479 BC) may be regarded as the foundations of a moral and philosophical tradition emphasizing filial piety and the moral duties of rulers and subjects, Confucianism has developed into a broader cultural and religious form that has influenced the development of all East Asian societies. While Confucianism has taken on overt religious manifestations in the ritual veneration of Confucius, its primary influences have been ethical and relating to the affirmation of social codes that underpin the existing order of society. Confucianism, besides emphasizing classical learning and the veneration of tradition, affirms the basic goodness of human nature and asserts that the ways individuals conduct themselves affects the basic social order at familial and wider social levels. This notion of individual spiritual responsibility for one's actions, and of the individual as a microcosm, in spiritual terms, of society at large has been central also to many of the East Asian new religions.

Taoism

Although originally a mystical tradition of meditation and passive withdrawal from worldly affairs, Taoism became associated with the search for longevity and the overcoming, through ritual and mystical practices, of the physical limitations of the body. Taoist practitioners in China sought, through the study of alchemy, to find the elixir of life, and they formed cults venerating that deities symbolized longevity. Taoism also developed complex systems of divination and fortune telling which were central to its appeal beyond China. Taoist ideas spread across the region in tandem with other Chinese cultural influences, including Confucianism, Buddhism, and the Chinese writing system. In Japan, Taoist influences were subsumed within the broader cultural sweep of continental culture and it never assumed its own distinct religious form there. However, its influences were pervasive, especially in terms of divination and magical practices. The early Japanese Imperial Court, e.g., developed a Bureau of Divination using Taoist techniques to predict and govern state affairs, while popular divination practices derived from Taoism remain widespread in Japan.

Indigenous Traditions: The Case of Shinto

Although Shinto, literally 'the way of the gods,' is often termed an indigenous Japanese religion, it is more accurately considered as a localized tradition that developed in conjunction with and in antithesis to the foreign religion of Buddhism which entered Japan from the sixth century onwards. The native religious tradition of Japan prior to the entry of Buddhism centered around the worship of local gods such as clan tutelary deities who were guardians of communities and clan lineages. This loose-knit local tradition acquired a specific identity with the entry of Buddhism. Even the term Shinto first came into existence after the incursion of Buddhism, as a means of differentiating the local from the imported tradition. Shinto is, thus, an example of a tradition that developed in response to (and hence in conjunction with) another, external religion, a point that has been emphasized consistently by influential Japanese scholars such as Kuroda Toshio.

Shinto is based in concepts relating to the *kami* – a term usually translated as god or deity, but implying a spiritual life-giving force. *Kami* may be associated with specific natural phenomena or landscape (for in Shinto, the entire world of Japan is considered to be the creation of the *kami* who give life to and animate it) but they may be spiritual entities that embody particular virtues or capacities and that can, if suitably beseeched and venerated, bestow blessings. The Shinto pantheon contains many thousands of *kami* from localized deities to ones of national influence. *Kami* may also be the spirits of humans of note or special accomplishments, such as Sugawara no Michizane, the ninth century scholar whose spirit is venerated as Tenjin, the *kami* of learning.

Shinto, Buddhism, and Religious Integration in East Asia

Interaction rather than conflict between Buddhism and Shinto has been a core theme in Japanese religious history. Buddhism's strategies of assimilation and accommodation have been nowhere more striking than in its dealings with Shinto and its *kami*. Since the *kami* were the guardians of the earth and the landscape, Buddhism adopted them as spiritual protectors of Buddhist temples: the striking vermilion Shinto gateway, representing entry to the *kami*'s sacred area, is rarely absent from Japanese Buddhist temple courtyards and, especially up to the nineteenth century, many religious centers were not so much Buddhist temples or Shinto shrines, but shrine-temple complexes combining both traditions. Many deities are also shared between the traditions, while this complementarity is manifest also in the roles Shinto and Buddhism play in the life cycles of individuals and communities. While Buddhism deals with death rituals and the memorialization of ancestors, Shinto is associated with beginnings and growth. The Shinto gods guard over the beginnings of life and are called upon for protection and support when babies are born and as infants grow: the *miyamairi* rite in which newly born children are taken to shrines to be placed under the protection of the Shinto gods,

remains widely followed in Japan, as is the *shichigosan* festival in November when children of seven, five, and three are given further ritual blessings.

This functional integration, in which Shinto deals with birth and life and Buddhism with death and the hereafter, has strengthened both traditions in the Japanese system. It is not a pattern limited only to Japan, for a dominant characteristic of the religious structures of the entire region has been that of integration of a number of traditions in the lives of the people. Thus, a state official in premodern China might be involved in Confucian rituals at work, Taoist divination rites and practices in his family life, and Buddhist funerary rituals when someone died, while in Korea, too, similar patterns (Confucian public rituals, the use of shamans and diviners for personal concerns, and Buddhist death rituals) could be discerned. It has only been in recent times, with the emergence of exclusive religious groups, such as the evangelical Korean protestant sects and a number of Japanese new religions that refuse to condone traditional religious practices, that this integrative pattern has been challenged. For the majority, however, it remains dominant.

Festivals and the Ritual Calendar

Shinto illustrates the close interaction of religion, festivity, and the calendrical cycle – a theme that permeates much of East Asian religion. Its festivals (*matsuri,* meaning both prayer and celebration) were traditionally a central element in the lives of local communities, and in modern Japan they remain a colorful and vibrant element in the calendar, involving a mixture of sacred ritual and spectacular festive entertainment that may include processions, dances, fairs, tourist attractions, and much celebratory eating and drinking. The most widespread of all such festivals is New Year when people make a first visit of the year to a shrine (*hatsumôde*) to thank the gods for blessings received in the past year and for protection and good fortune in the coming year. Many people also visit Buddhist temples at this time. *Hatsumôde* is highly popular and, since the 1970s, has been performed by a growing number of Japanese: numbers have risen from around 30 million in the late 1950s to around 85 million (out of a population of 120 million) in the 1990s. The growth of *hatsumôde* numbers is not isolated: Japanese scholars have noted a growth in participation in customary religious ritual activities between the 1950s and the early 1990s, and this has led them to question the validity of secularization theories and to show that these do not necessarily have universal validity.

However, such growth masks a shifting pattern within Shinto, in which small, rural shrines have declined due to rural depopulation and because people have preferred to visit better known and more identifiably national shrines further a field. Partially this has been a result of the development of an advanced transportation system but also because, as localized community structures have broken down or been transformed due to changing life patterns, people have sought their primary focus of identification in the national community. Hence, while they once would have performed *miyamairi* and *hatsumôde* at local shrines, tying themselves to local communities and deities, they now do these at shrines of national significance, an act that confirms their identification with the wider national community and reaffirms, in an age of internationalization in which the primary forms of comparison in terms of identity are across national rather than regional or local lines, their sense of Japanese identity. Many nationally well-known shrines receive many millions of worshippers at festival times: Meiji shrine in Tokyo, for instance, receives around four million visitors at New Year.

Shinto, Mythology, National Identity, Nationalism, and the State

The connection between Shinto and national identity indicated by recent patterns of shrine visiting points to a deep-seated characteristic of religion in the region: the close connection of religion, state, and identity. Here, again, Shinto is a striking (if particularized) example. Its myths attribute the creation of Japan and the origins of the Japanese people and its Imperial dynasty to the *kami*. In these myths the Imperial family are ordained divinely to oversee the nation, as they are descended from Amaterasu, the Sun Goddess, who is venerated at the great shrines of Ise, the most important shrines in Japan. The *kami* are the procreators of Japan and its people, who thus exist in a special, unique relationship to their gods and land. This special relationship is central to Japanese concepts of identity and has been associated closely with Japanese nationalism since the Meiji Restoration of 1868, when Japan developed a modern-style sense of nationhood by using Shinto and its mythological links to the Emperor as a focus of national unity and as a means of emphasizing national uniqueness as a chosen people and land. The association of Shinto and the state helped create a myth of racial superiority which legitimated Japan's colonization of Taiwan and Korea, involved the suppression of other religions and played a major part in Japan's fascism and war mongering in the first half of the twentieth century.

In the postwar era, official links between Shinto and the state have been barred under the Constitution, Japan has become a secular state, and Shinto exists predominantly as a shrine-centered tradition based around life cycle and other rituals and festivals. Nevertheless, there remain many people (especially of right-wing persuasion) and many Shinto priests who aspire to a return to a formal association between Shinto and the state. Many of the discussions of Shinto in the modern age thus center around issues of religion, nationalism, and politics.

Underlying Structures and Common Themes – Folk Religion

Although the above-mentioned religions are the most visibly identifiable older traditions of the region, they are underpinned by a pervasive folk tradition. It is a common argument of scholars from the region (e.g., Miyake Hitoshi in Japan) that this amorphous folk religion of shared customs, attitudes, beliefs, and practices deeply rooted in everyday lives and concerns of the people, forms the foundational religious structure of the region. Indeed, many of the ideas and themes that are central to the new religions derive directly from these folk religious foundations, while the new religions themselves

have been analyzed widely as modern articulations of the folk tradition. The folk tradition has also been the filter through which the historical religions of the region have been adopted by and adapted to local cultures. Those religions that have best developed strategies to accommodate or work with this tradition have been the ones which have transplanted most successfully to or developed in the region: examples include Buddhism, whose strategies and doctrines of accommodation have enabled it to absorb and work with local customs, and (in a reverse case) Christianity, whose inability to accommodate or accept folk religious beliefs and customs, notably relating to the ancestors, has proved a major impediment to its growth in much of the region.

The importance and vitality of this folk tradition is such that it has been a major focus of academic study in the countries of the region. Folk studies (or folk religious studies) are a primary academic discipline in Korea (where shamanism, as the cornerstone of the folk and native religious structure, has received especial attention) and Japan, and is generally accorded greater weight as an academic discipline than in the West. It is not just concerned with the indigenous traditions of folk religion; Japanese scholars such as Sakurai Tokutarô (shamanism), Miyake Hitoshi (mountain religion), and Shinno Toshikazu (pilgrimage and legends) have been concerned to map out and discuss the interactions of folk religion and Buddhism, and to demonstrate that 'folk religion' as manifest in Japan should not be discussed solely in Japanese terms but placed in a wider context. Making use also of Western academic studies of religion, scholars such as Miyake have demonstrated the potential universality of folk religious models, as well as broadening the comparative and potentially universalizing dimensions of Japanese scholarship of religion.

Themes of East Asian Folk Religion

The varying elements associated with the East Asian folk religious tradition(s) include emphases on calendar and ritual cycles relating to individuals and communities, the prevalence of shamanic beliefs and concepts relating to the role of spirits (including the spirits of the dead), spirit possession, healing, and the analysis of misfortune and provision of healing, the veneration of ancestors, and various this-worldly beliefs and customs relating to seeking assistance and amelioration in this world.

All these exist alongside or interact with the major traditions or are manifest in and expressed by them. Concepts relating to the spirits of the dead and the ancestors are deeply rooted in the folk religious arena, but the ritual services related to death and the ancestors are most commonly performed through the medium of Buddhism, whose success in East Asia has depended greatly on its ability to adapt to and accommodate folk beliefs in this area. The importance of the ritual calendar and the notion of the yearly cycle of festivals and rituals, originally based in the folk tradition and centered around agricultural rites, has already been mentioned in the context of Shinto in Japan, but it extends throughout the region in differing forms.

Perhaps the most predominant beliefs in the folk tradition relate to psychic interpretations of causation (of illness, misfortune, and, indeed, good fortune). Beliefs that this world does not exist in isolation but is influenced by other realms, and that those living in this world can be affected by the actions of spirits, mean that, in folk terms, any problem or event may be seen as having spiritual as well as physical causes. Thus, an illness may have psychic causes (e.g., the actions of an unhappy spirit) as well as physical (e.g., the effects of germs) ones, and hence solutions to problems require spiritual attention (e.g., ritual performances, acts of penance) to deal with its spiritual aspects. A strong shamanic tradition has existed throughout East Asia, in which spiritual healers (very often female, and with claims to be able to either travel between this and the spiritual world, or to make contact with it and find ways of appeasing the spirits who are afflicting the living) play a major role. This shamanic tradition is perhaps the most ubiquitous element in the Korean religious universe, but it also remains important in the rest of the region. Studies of Japanese religious behavior in modern times show that people are far more likely to turn to a local healer or diviner than to a Buddhist priest when they have personal problems. This loose-knit tradition of healers and diviners serves also as a counterbalance to the formal religious systems of Buddhism and Shinto, whose priesthoods are almost entirely male, and provides a mode of religious expression for spiritually inclined females, who have remained marginalized in the formal traditions. By contrast, the vast majority of shamanic spiritual healers in Korea and Japan are female.

Millennial Themes in East Asian Religious Culture

An important theme in East Asian religion that shows how religious ideas may be expressed across the various traditions and cultures of the region relates to millennial beliefs and expectations of future worldly salvation. These are found throughout the region, articulated through the folk religious traditions, Taoism, Buddhism, and, more recently, the new religions. Expectations of a new dawn, the arrival of a spiritual kingdom on earth, and/or the appearance of a celestial or spiritual savior who will bring justice, redeem the sick, punish the unworthy, and transform or renew the world have been especially potent in China, sometimes with Taoist influences but often associated with Buddhism, but they have emerged in Korea and Japan as well. In China, various Taoist-inspired movements such as the second century CE Way of Great Peace movement have rebelled against the state in the hope of establishing a new paradise on earth, while Buddhist-inspired movements have also been inspired by the concept of imminent salvation on earth, often centered on the future Buddha Maitreya (whose cult also inspired similar millenarian impulses in Japan). In China, too, there have been repeated uprisings of the millennial White Lotus Society, which combined Pure Land Buddhist ideas along with folk, Taoist, and other elements, while the Pai Shan-ti Hui movement, which incorporated Christian ideas and sought to create a heavenly kingdom of eternal peace on earth, caused the bloodiest and most dramatic of all such millennialist uprisings, the Tai Ping rebellion of 1849–64 which claimed millions of lives.

Millennial themes are prevalent in many of the new religions. In Korea, numerous religious movements have fused extreme forms of evangelical Protestantism with dramatic

millennial visions. The Tami Church (known also as the Mission for the Coming Days) attracted attention when it announced that the apocalypse would begin on October 28, 1992 and that its members would be raptured up to heaven. While this case of failed prophecy damaged the Tami Church, it has not dampened the emphasis on apocalypticism, which remains a central theme in much of Korean Protestantism, and which forms one of its cardinal attractions for the local populace.

The most striking manifestation of millennialism in Japan has been in the new religions that have arisen since the mid-nineteenth century, initially through the actions of charismatic female religious leaders such as Nakayama Miki (1798–1887) of Tenrikyo and Deguchi Nao (1837–1918) of Ômotokyô, but most recently among the 'new' new religions of the late twentieth century, many of which have emphasized that the world is at a critical turning point in which the old, materialist civilization will be swept away as a new spiritual world dawns. While many of the adherents of earlier millenarian movements were poor and disadvantaged, and the thrust of their movements was initially towards seeking social justice, the beliefs of the latest wave of new religions have been conditioned more by concerns that this world is facing extinction because of nuclear or environmental problems, and that a spiritual revolution is essential in order to avoid destruction. The most dramatic and famous of these later millennial movements was Aum Shinrikyô, which believed that a final war between good and evil was inevitable and in which the vast majority of humanity would be wiped out prior to the advent of a more spiritually oriented world.

New Departures: The New Religions

Since the mid-nineteenth century massive economic development, the impact of Western influences, and immense social change and population movement have produced recurrent tensions between traditional social, cultural, and religious structures, and the individualizing patterns of modernity. In religious terms, the most striking sign of such tensions and developments has been the emergence of new religious movements throughout the region. This phenomenon has been most pronounced in Japan but is discernible also in the rest of the region.

The new religions have generally been eclectic, drawing on the primary religious inspirations of the societies in which they have emerged: Korean new religions, e.g., might draw on Buddhism, shamanism, and Confucianism, while Shinto (along with Buddhism and the folk tradition) is a source of inspiration for many Japanese new religions. In very recent times, influences have come from outside the region as well, with evangelical Christian movements especially prominent in Korea and new-age themes appearing in the most recent new religions in Japan.

The new religions have been especially effective in dealing with the tensions between modernity and tradition, through their articulation of many aspects of traditional folk religious belief (e.g., concepts of psychic causation) in ways that fit with the needs of individuals in the modern world. They have flourished mostly in the growing conurbations of East Asia, providing a new sense of belonging and community identity for populations that have moved from rural areas to the cities for work reasons. While providing individual solutions to problems and focusing on understandings and definitions of the self in modern terms, they have equally emphasized tradition, reaffirming many of the social parameters of traditional culture and morality. The solutions they pose to individual problems center around shamanic concepts of spirit possession and magically-charged healing rituals, but combined also with reaffirmations of traditional moral structures and obligations, notably Confucian ethical values of filial piety. A typical example taken from a new religion in Japan might be that a personal misfortune or illness is the result of having neglected to perform appropriate rituals for one's ancestors and of causing their wrath: this breach of ritual propriety is a moral lapse which needs to be rectified through repentance and self-reflection, as well as participating in healing rituals. As such many of the new religions display a pronounced interweaving of magical practices alongside affirmations of morality; as various Japanese scholars have noted (e.g., Shimazono 1992), rather than magical practices decreasing as ethical and moral considerations become more strongly emphasized, the Japanese new religions show that the two often operate in tandem, the latter increasing and being articulated more pronouncedly as magical practices become more widespread.

The region's new religions almost invariably owe their origins to the charisma and inspirational leadership of individuals who claim to have direct contacts with other realms or to bring new revealed truths to the world. While serving as a medium for a newly revealed deity, however, a common pattern is that the charismatic leader gradually displaces the deity as a source of inspiration, authority, and worship, often becoming regarded as living deities and venerated accordingly. Their charisma, however, may continue after death, a point often emphasized by Japanese scholars interested in the study of charisma: authority and succession to the leadership generally (following traditional East Asian familial patterns) passes through the family lineage to a son or daughter, suggesting that charisma is in part related to the concept of blood and lineage, and the deceased founder becomes an even more central figure of worship, with their mausoleum often becoming a pilgrimage center for the religion.

Aum Shinrikyô: New Religions and Violence

In 1995 world attention was directed towards the millennial Japanese new religion Aum Shinrikyô and its blind charismatic leader, Asahara Shôkô, because of its nerve gas attack on the Tokyo subway. While Aum was not the first or only religious movement in East Asia in modern times to commit acts of violence the sensational nature of the subway attack, Aum's use of chemical weapons, and the subsequent evidence showing that it had engaged in a protracted series of crimes emanating from its religious activities and beliefs, caught the attention of defense and law agencies as well as scholars world wide.

The Aum affair has special significance for the sociological study of religion for many reasons. It showed similarities with

patterns of violence that manifest in other religious movements in the West (e.g., the Peoples Temple, the Rajneesh movement, and the Order of the Solar Temple) and appeared, in an extreme form, to fit into a wider pattern of the production of violence within certain forms of newly formed charismatic, world rejecting millennial movements. It provides a dramatic case study for those interested in the relationship between religion and violence, and several of those who have studied Aum have interpreted it as an example of the violence-producing dimensions of religion (e.g., Shimazono 1997, Reader 2000). As an example of how new religions can produce violence primarily because of their doctrinal orientations and internal dynamics, the case of Aum provides a significant counter-example to the arguments widely held by many scholars of new religions in the West, that movements that engage in violence do so primarily in response to excessive external pressures placed on them by a hostile society.

Scholarship on the New Religions and the Problem of East Asia

Mention has been made of the scholastic traditions in the region, especially of Japan, and some of the analyses and ideas they have transmitted. The new religions of Japan provide a case in point where work done by Japanese scholars has added to the wider understanding of new religions across the globe. Japanese scholarship generally has examined the 'new' new religions in the context of late twentieth century urban society and modernity, and as such has thus recognized, either explicitly or implicitly, the parallels that could be drawn between Japan as a first-world, modern, and technological society, and Western countries. Western scholars specializing in new religions have also been drawn to comparative studies of the Japanese new religions because of these recognizably common influences and factors. Much of the best Japanese scholarship on the new religions of Japan has taken account of Western theoretical perspectives, while many of the scholars in Japan have worked closely with Western scholars of new religions, mutually influencing and being influenced by them.

This has placed contemporary Japanese scholarship on the new religions in an international framework, and has made Western scholars more than ever aware of the importance, when seeking to develop comprehensive or universal models and categories in the study of religion, of the Japanese situation. Certainly no sociologist of religion concerned with the rise of new religions in the modern world can ignore the work being done in this field in and relating to Japan, just as no student of religious violence or of millennial movements could afford not to take note of Aum Shinrikyo. However, the corollary of this development has been to separate out Japan from the rest of East Asia in terms of the study of new religions: rather than viewing parallels within the region, e.g., Japanese scholars (and Western scholars working on Japan) have tended to examine Japanese new religions in the comparative context of Western new religions. This, however, means that the (potential) parallels between Japanese new religions and those of the rest of East Asia are focused on less clearly.

In other words, the problematic question raised earlier about how far one can discern or discuss the region in broad terms, is in some areas being answered in practical terms by contemporary scholastic work in and centered on Japan, which associates Japan far more with the industrialized West than, and thereby draws implicit boundaries with, the rest of geographical East Asia. While this does not invalidate the conceptual category or notion of East Asian religions, it does indicate the problematic aspects of talking of the region in any uniform sense. Not only do the traditions themselves take on different guises in the different parts of the region, but the manner in which they may be studied and the lessons that may be drawn from them may also highlight questions of difference rather than commonality. To what extent future studies will further add emphasis to the issue of difference and challenge the viability of treating the region as an entity is a moot question of great interest and significance to the field as a whole.

Abstract

A large number of Hindu religious traditions refer, positively or negatively, to a set of religious books, called the Vedas. These scriptures were, originally, the intellectual property of a priestly caste of Brahmans and the basis of their rituals and philosophies. Buddhism, Jainism, and Sikhism are major Indian traditions which explicitly reject the authority of the Vedas and the social and ritual hegemony of Brahmans. Islam and Christianity are major traditions in India which have been increasingly stigmatized by Hindus as 'foreign' to Indian civilization. In the modern period, the expansion of the colonial state is crucial for defining the location of religion in India. The general pattern in all Indian religions is that modern movements attack traditional priestly leadership, so-called 'backward' popular religion, and emphasize free, lay access to scripture and to religious debate. In this way, the foundation of religious authority changes and becomes mediated by education and new forms of communication, such as print, and later radio and television. This development also entails a growing participation of religious movements in modern mass politics. The greatest competition in the political arena is between Hindus and Muslims and has led to the partition of British India into India and Pakistan. Hindu nationalism needs to construct a Hindu majority in India, but runs counter to a number of anti-Hindu and anti-Brahmanical movements. Especially in the 1980s and 1990s, it has been successful in launching campaigns against Muslims and Christians to bolster 'Hindu unity.' Not only Hindus, but also Muslims and Sikhs, have been increasingly active in the political arena.

Indian civilization contains a great number of religious traditions, such as Hinduism, Buddhism, Jainism, Islam, Christianity, and Sikhism. All these traditions have influenced each other and have become part and parcel of Indian civilization in one way or another. A large number of Indian traditions refer, positively or negatively, to a set of religious books, called the Vedas. These scriptures were, originally, the intellectual property of a priestly caste of Brahmans and the basis of their rituals and philosophies. Brahmans as a caste form the apex of a hierarchy of status categories which can be seen as an early form of the later much more elaborate Indian caste system. Buddhism and Jainism emerged around 500 BC in protest against the Brahmanical monopoly of Vedic ritual. They are essentially ascetic religions which have much in common with other speculative philosophies which continued to accept the authority of the Vedas. Buddhism spread from India to the rest of Asia, but became marginal in India, while Jainism did not expand outside of India, but continued in India as the religion of, primarily, businessmen. Christianity came to Kerala in the first centuries of the Common Era and in other varieties with the Portuguese to Goa in the sixteenth century and with other Europeans in the centuries thereafter. Islam came to India at the end of the first millennium, along the coast with traders and in the northern plains as an element of the military and religious expansion of a variety of groups from West and Central Asia.

Hinduism

The majority of the Indian population today calls itself Hindu. Hinduism is a term that only in the eighteenth century came to be used for a variety of religious traditions which dominate the Indian religious landscape. When they are Brahmanical, these traditions refer to the Vedas, but when they are not they can refer to a number of religious texts, oral or scriptural. Gods like Vishnu and his reincarnations Rama and Krishna are very popular. Likewise, a god like Shiva, often represented in an aniconic, phallic form, is worshipped all over India. In many localities, one finds local manifestations of gods like Vishnu or Shiva. A special and important category of gods are Mother Goddesses which often protect against evil and diseases. The typical form of worship of images of gods is the offering of gifts like flowers or sometimes goats or buffaloes. These temples are serviced by Brahman or ascetic priests. Temples are everywhere, but especially in sacred places, which are somehow connected to the story of the god. Hindus make pilgrimages to these places, especially at auspicious times in the lunar calendar. There is also an elaborate complex of rituals which are performed in the domestic context, often related to moments in the life cycle. Finally, there are groups of priests, specialized in warding off evil and witchcraft and performing mortuary rites.

In terms of the social organization of religion, there are five elements in Hindu traditions. First, there is caste. Brahman groups have continued from the earliest times to dominate a large part of religious beliefs and practices. Ritual purity and sacred knowledge are the foundations of their supremacy. Other castes have also created cults of their own, but often they are seen of lower status than the Brahmanical cults. Second, there are rituals of kingship. There is the conception of a generic relationship between royal deity and human king which is reflected in ritual practice. In a large number of regions in India one finds a network of temples and palaces which are mutually interdependent. Third, there is the level of the village. The local community is often ritually represented in a number of festivals. Fourth, there is the notion of world renunciation. Ascetics have for a long time up to the twenty-first century built monastic orders and drawn lay support for their religious and worldly activities. They are innovators of religious traditions, but also, as free agents in village society, important long-distance traders, money brokers, and military entrepreneurs until the coming of the colonial state. Fifth, there is the concept of bhakti (devotion). One cult after another sprang up in India

during the second millennium, channeling waves of devotional enthusiasm. Often ascetic leaders were involved in this and in a number of cases they revolted against the Brahmans and the caste system. By that token they were sometimes able to find a distinct religious tradition, such as the religion founded by Guru Nanak, which evolved gradually into Sikhism and defined itself as different from Hinduism.

Hinduism is a term which has developed from 'Hindu,' a term used by Muslims who came to the river Indus or Sindh (from Sanskrit Sindhu) in the second half of the first millennium. 'Hindu' designates the inhabitants of this area of Al-Hind or Hindustan and their customs and beliefs. The term Hindu was made into an 'ism' by the British in the eighteenth century. The conceptualization of Hinduism as one particular religion among other religions and theoretically comparable to them can be understood in relation to a number of philosophical arguments about the universality of the category of 'religion' in the European Enlightenment. The conceptualization of their religious traditions by Hindus themselves had evolved along lines of philosophical argumentation about dharma (the sacred order of things) by religious scholars who are easiest divided in followers of the God Shiva and followers of the God Vishnu. Their philosophical arguments were often accompanied by ritual injunctions, especially for temple worship. Below this level of high philosophical argumentation there were a number of devotional movements which can broadly be divided into those which focus on the worship of images and those which have an aniconic image of God. The British introduced the essentialized and unified concept of Hinduism as a religion in an already existing arena of lively polemics about religious difference.

Modern Period

In the modern period, the expansion of the colonial state is crucial for defining the location of religion in India. In the eighteenth century, the British East-India Company followed a traditional policy of religious patronage benefiting the religious establishments in the areas which came under their growing influence. This policy was further supported by a strong interest in Hindu scripture from a viewpoint of comparative linguistics and comparative religion. This so-called 'orientalism' of the late-eighteenth century was vehemently attacked at home and in the colony by utilitarian administrators and evangelical missionaries who were united in their rejection of anything Hindu. In education and religious worship, the colonial administration was forced to withdraw from giving its patronage to religious establishments and a policy of 'religious neutrality' was established gradually in the nineteenth century.

The response of Indian religious thinkers, institutions, and movements to colonial interference under the aegis of religious neutrality has been central to the formation of modern religions in India during the nineteenth century. Especially attacks by evangelical missionaries on religious practices and social customs led to both reformist and conservative responses. In Bengal, Rammohan Roy (1772–1833) studied Christianity and felt great affinity with the rational critique of religious orthodoxy launched in Britain by Unitarians. In 1827, he founded the British Indian Unitarian Association, but his study of the Vedas and Upanishads quickly led him to explore the limits of Unitarian universalism. In 1828, he decided that a universal, rational religion had to be based upon the Vedas and Upanishads and created the Brahmo Samaj, a small, but influential elite movement, propagating a deist and universalist kind of religion, based upon Hindu sources. The movement is particularly opposed to 'superstitious customs' of 'ignorant people,' 'deceived' by their Brahman leaders.

Rammohan was in the forefront of public action. In January 1830 he, together with 300 residents of Calcutta, presented a petition to Governor-General William Bentinck in support of government prohibition of widow immolation, a practice found in some parts of India when after the demise of a husband the widow throws herself on the pyre of her husband to be burned with him. Rammohan rejected this practice on the basis of his reading of Hindu scripture. He distinguished authoritative sources, such as the Vedas, from other sources. It is significant that he did not refer to authoritative interpretations by learned Brahmans, but relied entirely on his own judgment. This is an important step toward the laicization of Hinduism, that is to say, the formation of religious movements, carried by lay believers and relatively independent of traditional, sacred interpreters of the Hindu canon. The Brahmo Samaj was the cradle of an intellectual Hinduism which was at the end of the century personified by Swami Vivekananda (1863–1902), the founder of the Ramakrishna movement.

Movements like the Brahmo Samaj are sometimes called Neo-Hindu because they have been clearly influenced by European thought and Christianity. On the other hand, however, they are also in direct interaction with more traditional thinkers and movements. A good example is the illiterate saint Ramakrishna (1836–88), a priest of a Kali temple near Calcutta whose devotional practices, ecstasies, and unconventional behavior was very attractive to the intellectual Brahmo Samaj adherents, because he seemed to signify a certain untainted Hindu authenticity. The great reformer Vivekananda took Ramakrishna as his spiritual guide.

Vivekananda became famous after his visit to the World Parliament of Religions which was organized in Chicago in 1893. He offered a packaged Hinduism, in which spirituality and yoga (mental and physical discipline) were keywords, first to a world audience and later to an audience at home. Central to Vivekananda's religious message is the notion of 'practical Vedanta,' in which he combined the Vedanta (= philosophical commentaries on the Vedas) with participation in social activism rather than with ascetic withdrawal from the world, as had been common in Hindu traditions. It is this message which could be tied up with nationalism and political activism as was done by political leaders such as Mohandas ('Mahatma') Gandhi (1869–1948).

Also outside of Bengal we see a number of movements which interact both with Hindu tradition and with modernity, as brought by colonial rule. The Arya Samaj is the most important among them. Founded by Dayananda Saraswati (1824–83), an ascetic who had been initiated in one of the most austere monastic orders in Hinduism, it is an iconoclastic movement which identifies image worship with the decline of an earlier pure Vedic religion. It attacked also the caste system and its system of marriage and the traditional Brahmanical priesthood. The Arya Samaj became and remains one of the central religious pillars of Hindu nationalism.

Public Sphere

It is not only Hinduism which is developing modern movements in the new public sphere created under colonial rule. The general pattern is an attack on traditional priestly leadership, on 'backward,' popular religion and an emphasis on free, lay access to scripture and to religious debate. In this way, the foundation of religious authority changes and becomes mediated by education and new forms of communication, such as print, and later radio and television. Muslim movements such as the Deobandis, the Ahmadiyyas, and the modernist Aligarh movement share with the Hindu movements of the period the defense of their religion against the onslaught of missionary criticism and the attempt to formulate an answer to modern intellectual challenges. Clearly, they are all deeply political since they mobilize people against certain aspects of colonial rule as well as against aspects of their religious traditions and traditional leadership. They are the basis for the formation of the Muslim political party, the Muslim League, and for Muslim participation in the Congress Party. Also the Sikhs have to respond to colonial modernity. The British gave the Sikhs preferential treatment in their recruitment for the army, which made the rather fluid Sikh identity both more valuable and more fixed. The Singh Sabha movement is especially important, since it challenges the control over the centers of Sikhism, the temples or gurdwaras. These centers were owned by hereditary priests, but following the general pattern of laicization the Singh Sabha movement demanded that they came under the control of the lay community of Sikhs. Control over the committee which governs these temples is still one of the biggest prizes in Sikh politics. It is also the basis of the power of the Sikh political party, the Akali Dal.

The twentieth century witnessed a further politicization of religious identity. The greatest competition was between Hindus and Muslims. The colonial state reinforced this competition by creating separate job opportunities, separate civil laws, and separate electorates. The advent of mass politics brought with it the mass mobilization of people on the basis of reified identities. Mohandas Gandhi, the great leader of the Congress party, was brilliant in his strategies to dismantle British power, but these strategies were based explicitly upon Hindu practices. Both he and, to a lesser extent, Jawaharlal Nehru were perceived by Muslims as Hindu despite their open secular politics. Radical movements emerged which challenge the idea of India as a plural civilization. 'To be an Indian is to be a Hindu' was a slogan of V. D. Savarkar (1883–1966), one of the founding ideologies of Hindu nationalism. Movements such as the Rashtriya Swayamsevak Sangh (RSS) and the Hindu Mahasabha wanted to establish Hindu hegemony in independent India. The assassins of Gandhi in 1947 emerged from such organizations. On the Muslim side, the Muslim League became gradually more and more radical until it demanded Pakistan, a homeland for Muslims, in 1942 and ultimately forced the Partition of India. The tragedy of the violently enforced migration of Hindus to India and Muslims to Pakistan, the division of East and West Pakistan which led in 1971 to the foundation of Bangladesh, the territorial dispute about Kashmir, and the threat of warfare between these two nuclear powers were all results of the political mobilization of religious difference on the Indian subcontinent.

Nationalism

Hindu nationalism needs to construct a Hindu majority among the Indian population to realize its claims to political hegemony. It runs not only against the resistance of non-Hindu religious communities, such as Muslims or Sikhs, but also against that of so-called 'untouchables' and 'tribals' who form a large minority in that section of the population which has to be constructed as a Hindu majority, but who are severely discriminated within Hindu practices. There are a number of anti-Brahman, and sometimes anti-Hindu, movements among these underprivileged groups which demand special protection and positive discrimination from the state. Most of these demands concern education and employment, but participation in Hindu rituals and access to temples are also important in the mobility of these groups. One of the most important movements among 'untouchables' was led by Bhim Rao Ambedkar (1891–1956), a Mahar untouchable from West India who has a doctorate in law from Columbia University. It was Ambedkar, one of the principal authors of the Indian constitution, who late in his life concluded that the untouchables would not be equal citizens in India as long as they continued to be second-rate Hindus. He led a mass conversion to Buddhism, primarily by his own community of Mahars, but also followed by other untouchable groups in India. The conversion to Buddhism, however, has not solved the discrimination of these groups in India and more recently a unifying tactic has been to claim a more secular, militant identity in terms of race rather than religion.

In Indian Islam, one of the major developments in the twentieth century was the founding of the Tablighi Jama'at in 1927 by Maulana Muhammad Ilyas (1886–1944). In 1934, Ilyas started a great revivalist campaign among Muslims of Mewat, an area near Delhi. Going from person to person, he called upon them to follow their Muslim duties, such as praying in the mosque. Gradually he formed groups of laymen who went for fixed periods on tours to invite their fellow Muslims to perform their duties. This created a snowball effect whereby more and more people became involved in this activity. The groups went around first in the area of Mewat, then in other places in India and Pakistan, and, finally, in the 1950s abroad to countries such as Nigeria, Morocco, Britain, Canada, and France. The movement thus spread from South Asians to other Muslims and is now one of the most successful Islamic movements in the world. The Tablighi Jama'at is professedly apolitical and in that way very different from the major Islamist movement of the subcontinent, the Jama'at-i-Islami. This movement was founded in 1941 by a former journalist, Maulana Maududi (1903–79), one of the most influential Islamist thinkers of the twentieth century. It is a much smaller movement than the Tablighi Jama'at, but highly political and organized as a tightly and hierarchically run revolutionary force which aims to capture the state in order to transform society according to Islamic principles. In Pakistan, it has a considerable influence in politics and also in the rest of the Muslim world revolutionary movements of the Islamist persuasion have taken it as an inspiring example.

The 1980s saw the development of some ultranationalist religious movements in India. The Vishwa Hindu Parishad, founded in Bombay in 1964 by some religious leaders with the help of the RSS, organized a country-wide protest against

the conversion to Islam of a group of 'untouchables' in the South Indian village of Meenakshipuram in 1981. The success of this protest led to the staging of another All-India campaign in 1984 to demand the demolition of a sixteenth century mosque in Ayodhya, in North India, which had allegedly been built on the site of a temple commemorating the birthplace of the God Rama. This campaign became one of the most important issues in Indian politics in the decade following its start. In 1992, the mosque was demolished with the tacit acceptance of the Indian state.

The 1980s also saw the development of a radical Sikh separatism in the Punjab, led by Sant Jarnail Singh Bhindranwale (1947–84), a young religious leader. His militant career started with intersectarian strife among the Sikhs, but developed into straightforward confrontation with the Indian state. In 1984 the most important Sikh shrine, the Akal Takht in Amritsar, was captured by the militants who demanded Khalistan, a separate Sikh state, imitating the earlier demand for Pakistan by the Muslims of South Asia. In the same year the Indian army decided to attack the Golden temple and chase the militants. The action caused great disaffection with the state among Sikhs worldwide and led to the assassination of Mrs Indira Gandhi (1917–84), the then prime minister of India.

During the twentieth century, there was a growing nationalization of Indian religions, which makes it difficult to separate them from processes of state formation. The migration of South Asians outside India has led to these forms of religious nationalism being spread to the rest of the world.

Also the relation between India and Pakistan is an important element in the development of religious nationalism. Especially the contested status of Muslim-majority Kashmir leads to continuous violence. In 2008 the Laskar-e-Taiba, a militant group based in Pakistan, executed a well-coordinated attack on Mumbai, killing 164 people and drawing international attention. One of the most important challenges of India today is to improve Hindu–Muslim relations.

Abstract

Religiosity, in the social sciences, is a term used to differentiate and describe both individual and collective attachments to religion. Religiosity identifies connections to religious traditions and differentiates subgroups or denominations within religious traditions to describe the personal attachments of individuals or the collective commitments of groups or nations. The diversity or homogeneity of religiosity in nations or groups can foster both solidarity and conflict. Individuals' religious commitments are associated with a host of social scientific outcomes, including social mobility, ethnic solidarity, and political commitments.

Religiosity is a characteristic of individuals and collectivities that displays various features of beliefs about the supernatural and how individuals and social groups engage in behaviors related to the supernatural. For individuals, supernatural explanations about the meaning and purpose of life and the trajectory of individuals and groups are often comforting and valuable (Stark and Bainbridge, 1987; Stark and Finke, 2000), and groups with common beliefs can enjoy social solidarity that enables collective action – whether for producing collective goods through social capital or eliminating competition through repressing those whose religiosity conflicts with the dominant group (Sherkat, 2005).

Individuals are socialized as young children by families and religious groups to understand and believe supernatural explanations about the meaning and purpose of life (Sherkat, 2003). In modern societies, these explanations are proffered by and connected to formal religious organizations, and individuals grow to feel a sense of common identification with the religious groups. The process of instilling beliefs in supernatural explanations also involves formal collective behaviors. Individuals participate in religious organizations and ritual actions that help reinforce supernatural beliefs and explanations and generate a sense of individual identification and collective identity.

Collective identifications with religious organizations and traditions provide definition of the religiosity of social groups, for both areal units (nations, regions, municipalities, and the like) or subgroups in a population, particularly ethnic groups. Social scientists often describe nations or regions as, for example, 'Christian,' 'Buddhist,' 'Muslim,' or 'Sikh' as a discernment of the type of religion predominating. Levels of religious participation and commitment are also definitive of collective religiosity, and are often used to characterize the quality and vitality of religious institutions. The importance of participation for institutional vitality makes it a useful characteristic of the concept of religiosity applied by social scientists to religious traditions, religious organizations, or areal units. Levels of religiosity are consequential for the mobilization of resources by religious groups, and these resources are used not only for religious purposes such as constructing religious buildings and staffing religious institutions with professionals and support personnel, but also for broader collective actions such as public works and charity, political mobilization, and religiously motivated social control (Sherkat, 2005).

Religious Traditions and Denominations

Religious traditions are constellations of beliefs, practices, and institutions used to describe a common type of religiosity. Religious traditions are broad understandings of the supernatural produced in societies and practiced by groups and individuals. Traditions espouse distinctive explanations, and in contemporary religious traditions these are codified in texts considered sacred by individuals and institutions that adhere to and produce that form of religion. Contemporary religious traditions include Baha'i, Buddhism, Christianity, Confucianism, Druze, Hindu, Islam, Jain, Judaism, Mormon, Sikh, Sufism, Taoism, and Zoroastrianism. In the history of religious traditions, most distinctive supernatural explanations have been extirpated as many cultures were destroyed through conquest – indeed, even in fairly recent history, we have minimal understanding of what the religious traditions were in many societies such as the Indigenous populations of the Americas and Australia, the non-Christian religions in early Europe, or the traditions we now call Hindu. Many traditions are formed by adding to the sacred explanations of an existing tradition. Social scientists define these movements as cult movements or new religious movements (Stark and Bainbridge, 1985, 1987), and so Christianity, Islam, and Mormon sprang as new traditions from Judaism, and Buddhism was a distinctive strand of Hindu. Other new religious movements are syncretic, and combine explanations of the supernatural from two or more traditions (e.g., Sikhism melds together Islam and Hindu, and Baha'i and the Unification Church syncretize from many traditions). Of course, over time it no longer makes sense to identify new religious movements as cults, and so traditions like Mormon and Baha'i are independent traditions. However, this is often contested, as early Christians identified as Jews, most Mormons consider themselves Christians, and Sufis identify as Muslims.

Beyond these broad traditions are more idiosyncratic interpretations of religious explanations within traditions. In Western social sciences, these forms of religiosity are conventionally referred to as denominations of a religious tradition. For example,

even the relatively new Mormon tradition is denominated by at least four organizations: (1) the Church of Jesus Christ of Latter Day Saints, (2) the Reorganized Church of LDS (now called the Community of Christ), (3) the Church of Jesus Christ, and (4) the Fundamentalist LDS. Denominations are formed through differentiation and schism over interpretations of supernatural explanations and conflicts over the control and use of religious resources. Denominational diversity is often difficult to assess in many religious contexts because local religious organizations may operate independently to interpret religious explanations. This is particularly true in Islam, Judaism, Taoism, Confucianism, and other religious traditions where religious leaders are free to interpret religion as they wish, and where there is minimal hierarchical control over the type of religious explanations put forward at the congregational level. Religious diversity is often examined using denominations as the unit of religiosity being examined (Finke and Stark, 1992; Iannaccone, 1991), and religious conflict is very often spurred by competition for control of traditions among competing denominations (e.g., Catholic–Protestant in Christianity, Mahayana–Theravada in Buddhism, and Sunni–Shiite in Islam).

At both the aggregate and individual levels, social scientists often use religious traditions to describe the religious commitments that predominate in nations, regions, or smaller geographic units or are held by individuals. Generally, however, this is a matter of convenience caused by a dearth of data that would enable a more exacting portrait of denominational distributions and identifications. Denominational data simply do not exist for most nations and areas, and many studies of individual religious commitments are limited to identification with religious traditions as the only indicator of religiosity.

Religiosity as Religious Behavior: Participation and Devotion

Religious collective action is a definitive element of religiosity. Religiosity is very often linked to levels of religious behavior in areas or by individuals. Religious behaviors can be public, as in participating in religious rituals, making pilgrimages, or donating time and money to religious groups; or they can be private, such as prayer, meditation, and reading sacred texts. In many religious traditions, public religious participation is routinized in regular religious rituals performed at a temple. This is particularly true for faiths springing from the Abrahamic tradition, where weekly ritual participation is prescribed for devotees and supported by institutional resources. In other traditions, however, ritual activities are mostly confined to the priestly class and lay members are expected to participate only on special holy days and festivals (as in Hindu and Buddhism).

Religious traditions or denominations that emphasize more irregular collective activities for lay members tend to amplify the value of engaging in personal prayer and devotion, giving money to temples and religious authorities, making pilgrimages to holy sites, and prescribing household shrines to facilitate religiosity. Sociologists often classify these types of traditions as 'devotional' rather than 'congregational' in terms of their form of religiosity. Devotional forms of worship are effective for satisfying religious desires when religious institutions lack the facilities and staff to serve the needs of large populations or devotees in rural areas. Congregational forms of religious organization become more common in urban areas and when religious resources are plentiful.

Religious traditions and denominations also vary in how they approach outsiders, with some groups having a conversion-oriented approach amplifying proselytization of the faith to outsiders, while other groups advocate separation from those who do not adhere to the faith. Proselytization is a form of religious behavior, and some groups (particularly the Jehovah's Witnesses, Mormons, Soka Gakkai Buddhists, and Bhakti Hindu groups) incorporate proselytization into their prescribed religious behaviors.

Religious Beliefs, Identities, and Personal Religiosity

Religious beliefs are a cognitive component of religiosity, are definitive of distinctions between different religious traditions, and are often consequential for distinguishing denominations within traditions. Beliefs as a component of religiosity often reflect the degree to which people believe in supernatural explanations – such as creation myths, gods and spirits, beliefs about prophesy, supernatural rewards and punishments, and the accuracy or divine authority of sacred texts. Beliefs that adhere strictly to particular interpretations of sacred texts and that claim exclusive understandings of supernatural explanations are indicative of fundamentalist religiosity. Social scientists are often interested in how beliefs change over time, and in the secularization of beliefs about the supernatural.

Studies of religious beliefs are problematic because of the peculiarity of religious beliefs within traditions and the gulf between traditions. There are commonalities in beliefs across the Abrahamic tradition – Jews, Christians, Muslims, and Mormons share core sacred texts with common creation myths, gods, and prescriptions and proscriptions for religiously sanctioned behaviors. Yet, Christians almost uniformly reject beliefs in the propriety of religious rules regarding dress, animal slaughter, and dietary proscriptions.

Religiosity is often linked to politicized or collective identities. Here, specific religious movements link to a more collective identity such as 'born-again Christian,' 'fundamentalist,' 'Evangelical,' or 'ultra-Orthodox.' These identifications may be associated with institutional ties, but individuals can choose to embrace or reject the identification without disrupting connections to a religious group. Politicized identities are often fickle, and in the United States we have seen 'fundamentalist,' 'born again,' and now 'evangelical' identities tied to religiosity and politics. Many treatments examine religiosity in terms of its relative degree of orthodoxy or fundamentalism. Here, researchers attend to whether religious beliefs adhere to literal textual interpretations of sacred texts in the tradition – or at least to contemporary interpretations of some aspects of those texts.

Contemporary research on European and American Christianity has argued that Western Christians increasingly 'believe but don't belong' or are becoming 'spiritual but not religious' (Davie, 1990). While this thesis has been given considerable play by journalists and religious pundits, social scientific investigations have consistently shown that people who do not belong to religious organizations tend not to believe, and

that many who do belong do not believe core tenets of the faith (Voas and Crockett, 2005).

Because of variations in religious beliefs across and within traditions, most examinations of beliefs focus on common indicators, such as the belief in gods, self-perceptions as being a religious person, or the importance of religion in people's lives. Studies find considerable diversity regarding beliefs about gods and personal religiosity. In the Czech Republic only 16% believe in a personal god, while the figure is 19% in Sweden and 24% in Japan. In contrast, 68% in the United States believe in a personal god, while the number is 72% of Chileans and 92% of Filipinos (Smith, 2012).

Macrolevel Dimensions of Religiosity

Across geographic space and over time, religiosity varies, and social scientific theories and analyses typically address how and why it varies from place to place and time to time. Of most interest have been secularization theories, which posit that religious institutions will lose influence as societies modernize, and that consequently indicators of personal religiosity will also decrease – such as religious participation, identification with religious groups, and beliefs in gods and the veracity of sacred texts (Stark and Bainbridge, 1985, 1987). More recently, religious market theories have focused on the importance of state-level regulation for influencing religiosity, and on the importance of normative pressures to consume religion (Finke and Stark, 1992; Iannaccone, 1991; Sherkat and Wilson, 1995). Finally, religiosity is often intertwined with ethnicity and language, and ethnic nationalism and regionalism are often prime motivations for collective religiosity (Beyer, 2006).

Secularization theorists have long argued that, as societies became more differentiated and more modern, widespread education would undermine beliefs in supernatural explanations, thus leading to declines in religiosity (Berger, 1965). In Europe and Japan, this appears to have taken place, and religious hegemonies have been shattered. However, elsewhere in the world, religion remains a powerful institution and religiosity remains high. Some nations were deliberately secularized through state control and regulation of religious institutions, particularly in the former Soviet Bloc and China. However, the breakup of the Soviet Empire and the fall of socialist states led to decreased religious regulation and an increase in religiosity in those nations (Froese, 2008; Froese and Pfaff, 2001).

Supply-side religious market theorists have explained the rise and fall of religiosity by arguing that the state regulation of religious firms and state sponsorship of religion have decreased religiosity (Iannaccone, 1991; Stark and Finke, 2000). From this perspective, religiosity is motivated by having access to high-quality religious goods – religious explanations imbued with certainty instead of doubt, and enthusiastic religious participation rather than formulaic ritual. Supply-side theorists argue that when states constrict religious products or attempt to produce a homogeneous religion, it undermines the quality of religious goods and reduces overall rates of religiosity. At the individual level, supply-side market theorists argue that religiosity is a function of religious human capital, defined as an understanding of how religion is produced in particular settings. When individuals have high levels of religious human capital, they are able to collectively produce valued religious goods; however, if their religious capital is incompatible with existing religious resources (i.e., a Hindu in a Catholic setting), there will be minimal religious production and low levels of religiosity (Iannaccone, 1990).

Ethnicity and nationalisms also influence and are influenced by religiosity. Many ethnic groups across varied religious traditions embrace religious participation and the expression and promulgation of religious beliefs in order to sustain ethnic identity and motivate political salience (Beyer, 2006). In multiethnic nations, religiosity is often used as a marker of ethnic commitment, and in the presence of political persecution religiosity is often an oppositional activity motivated by ethnic commitments and political ties as much as by an individual or collective desire for supernatural explanations, rewards, or compensators (Froese, 2008; Froese and Pfaff, 2001).

Microlevel Processes and Religiosity

Most social scientific studies of religion focus on individual religiosity and the microlevel processes that inform the intergenerational transmission of religiosity, variations in religiosity over the life course, and the consequences of personal religiosity across a range of social behaviors and institutions. Life course processes are an important focus of research examining variations in religiosity, and the connections between religion and marriage, fertility, and career trajectories are the focus of a substantial body of research, particularly in the United States and Europe.

Religious participation and devotion are often linked to life course events such as marriage, childbirth, childrearing, and death. The formation of a family through procreation is sacralized through religious rituals of marriage, and religiously sanctioned marriage is an aspect and indicator of religiosity. Children are often dedicated to religious traditions at birth or in early childhood through ceremonies of baptism or ritual cleansing, and through training and confirmation of religious fealty. Life course transitions like school graduations, obtaining employment, and purchasing a home or a car are also often marked by religious rituals. Religious funerals are another indication of religiosity, and many religious traditions have particular prescriptions and proscriptions regarding the burial or disposal of dead bodies of the faithful.

The socialization of children often gives rise to higher levels of religious engagement, particularly in traditions where congregational styles of worship predominate. Longitudinal studies show that marriage and childrearing have a positive impact on religious participation, particularly when the age of marriage and the timing of children follow a normative pattern for these life course events (Stolzenberg et al., 1995; Sherkat, 2003). Religious identifications, beliefs, and patterns of participation are passed from parents to children, and the family of origin is the most important source of religious socialization (Sherkat, 2003; Sherkat and Wilson, 1995). Religious socialization also happens within religious institutions, and some sectarian religious groups demand higher levels of public religious expression and more exclusive religious beliefs.

Retirement and the departure of adult children from the household may also provide opportunities for religious participation and pilgrimage, and even to join religious

societies or train for the clergy. Aging also appears to be positively associated with the certainty of beliefs about gods (Sherkat, 2010); however, it is uncertain whether this is true outside of the United States.

Individual-level religiosity is also structured by ethnicity and gender. In many areas of the world, religion is a cultural marker of ethnic status, and religious participation is often highly valued or mandated in those groups (Ellison and Sherkat, 1995). In many religious traditions, women are substantially more active than men, particularly in Western Christianity (Sherkat, 2003), and there has been considerable debate in the literature about the origins of gender differences in religiosity.

Educational institutions and attainment processes also influence religiosity and religious beliefs. In the United States, higher levels of education are associated with higher rates of participation and less exclusivist and more secular religious beliefs (Sherkat, 2003). Religious schools play a role in securing particular religious commitments through childhood socialization and the homogenization of social networks. Individual or family religiosity will influence educational choices, and can lead to higher or lower levels of attainment depending on how religiosity is seen to conflict or correspond with educational goals (Sherkat, 2010). In the United States, sectarian Protestants consistently show educational disadvantages, while Jews and liberal Protestants have high levels of attainment (Lehrer, 2004; Fitzgerald and Glass, 2008). These educational trajectories also influence occupational attainment, income, and wealth, and are linked to patterns of early marriage, patriarchal gender norms, large family size, and anti-intellectualism (Keister, 2011; Darnell and Sherkat, 1997; Sherkat, 2010).

Religiosity also plays an important role in political engagement, structuring preferences for political goods and influencing ties to political organizations. Individuals' social networks are strongly influenced by religiosity, and the pattern and strength of these ties can be used as resources by political movements (Sherkat, 2005). Religious beliefs are increasingly important for informing beliefs about political goods associated with modern states – particularly the value of education; equality across ethnic, religious, and gender groups; and the sanctity of religious strictures and regulations on social life (blasphemy laws, regulation of food and drugs, clothing regulations, limitations on the depiction of sex, and the like) (Jurgensmeyer, 2008).

Future Directions in Religiosity Research

The study of religiosity has been enlivened by the continued importance of religiosity for modern political and social conflicts, and by the increasing diversity of religious expressions throughout the world. The globalization of religious diversity is evident even in heavily regulated religious environments like Saudi Arabia. Yet, the study of religiosity has not kept pace with this global diversification. Indeed, we lack adequate classification systems to describe religious diversity in many environments – we cannot distinguish diverse types of Muslims, Buddhists, or Hindus, for example. Religiosity has not been adequately examined from a social scientific perspective in most parts of the world, and most social scientific data collection efforts have given only perfunctory attention to how to measure religious commitments. The collection of data on religion remains controversial and potentially deadly in much of the world, and this hampers our understanding of how religiosity plays a role in social life in those areas. The problem is not solved even in well-studied environments like the United States. Many studies and data collection efforts give limited attention to religiosity and provide scant information on religious commitments and beliefs.

Religiosity and Prejudice against Minorities

Peer Scheepers and Rob Eisinga, Radboud University Nijmegen, Nijmegen, The Netherlands

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The authors delineate two broad streams of research, one more psychological focusing on intrapersonal religious orientations and the other more sociological focusing on extrapersonal religious dimension, both concerned with the religion and prejudice against ethnic minorities. The authors discuss robust relationships that in the course of nearly 60 years of research have been discovered. They focus on and find dimensions of religiosity that 'make and unmake prejudice,' in line with the classic and paradoxical statement of Allport.

Introduction

Just after World War II, a crucial research question was developed and answered by Allport and Kramer (1946) on the relationship between religiosity and intolerance toward minorities. They found some evidence that the more religious people supported prejudice. This finding was considered surprising but also distressing, particularly in the wake of the war that had been accompanied by widespread prejudices against different minorities, both ethnic (particularly Jews) as well as sexual (particularly homosexual) minorities and had culminated in the genocide of so many innocent victims during the Holocaust. Ever since then, this socially relevant question has been on the research agenda of generations of researchers, particularly in the decades following the war, has and increasingly as patterns of immigration have brought diverse religious groups together.

Allport summarized numerous findings on this relationship in his contributions in the late 1950s and early 1960s, stating: "… there is something about religion that makes prejudice and something…that unmakes prejudice…" (1958,1966: p. 447). At regular intervals, overviews of the empirical relationship between religiosity and prejudice were published and several of these were frequently cited (Gorsuch and Aleshire, 1974; Chalfant and Peek, 1983; Batson et al., 1993). Five decades after the initial study, Hood et al. (1996: p. 359) again concluded that the massive evidence justified a broad generalization: "…the more religious an individual is, the more prejudiced that person is…"; however, they followed this generalization with many qualifications based on different dimensions of religiosity as well as by varied targets of prejudice.

After analyzing the numerous contributions, also including recent overviews, the authors distinguish two broad disciplinary traditions that have focused on these different dimensions of religiosity. In a more psychological tradition, researchers have focused predominantly on (intrapersonal) religious orientations, whereas in a more sociological tradition, researchers have focused predominantly on (extrapersonal) religious dimensions. The authors review and describe these theoretical considerations and empirical findings as related to intolerance toward ethnic (and sexual) minorities.

Psychological Studies

Religiosity in this tradition goes back to religious orientations, initially introduced by Allport and Ross (1967) as extrinsic versus intrinsic orientations. They found that those people with an intrinsic orientation, for whom religiosity served as a dominant master motive in their daily lives, were less prejudiced against minorities than those with an extrinsic orientation, for whom religiosity served as a means to an end. Intrinsically motivated religious people were considered to be more tolerant because they 'lived' or at least supported religious teachings on brotherhood of man and rejected contempt of other groups in society. The initial findings have been replicated numerous times, at least until the mid-1980s (Spilka et al., 1985). These religious orientations were additionally refined by Batson (1976) who introduced the quest orientation, an orientation to be ready to face existential questions and acknowledge religious doubts. People who were motivated by a quest orientation were considered to be more tolerant because they were ready to search for independence of (informal) religious teachings or shared collective religious norms on other ethnic groups. Thereafter, this tradition was enriched by theoretical notions on religious fundamentalism, developed by Altemeyer and Hunsberger (1992). They proposed that religious fundamentalism, an orientation reflecting an unquestioning and unwavering certainty in basic religious truths, would encourage fundamentalists to discriminate between those living according to these truths versus those who do not, and, moreover, to condemn and reject members of other religious or ethnic groups.

Recent meta-analytic overviews by Hunsberger and Jackson (2005) and Hall et al. (2010) showed highly consistent results: religious identification, religious fundamentalism, and extrinsic orientations show strong positive associations with ethnic intolerance, providing evidence to the above-mentioned theoretical propositions. On the other hand, they found that intrinsic and quest orientations showed negative associations, also in line with the above-mentioned theoretical expectations. In sum, these findings are evidence for the classic claim by Allport about religiosity inducing and reducing intolerance. Moreover, additional evidence showed that the relationship between religious fundamentalism and intolerance was explained by authoritarianism (Eisinga et al., 1999; Hall et al., 2010; Johnson et al., 2011).

In their meta-analysis of numerous studies over several decades, Hall et al. (2010: p. 131) also estimated the overtime variation in the association and actually found that "the positive relation between extrinsic religiosity and racism decreased significantly in recent years," and this also held for the relationship between religious fundamentalism and racism (2010: p. 132). A serious drawback of these findings is that they have been based predominantly on small, nonnational, and selective samples, and many of the studies are of college students, and this truncated factors such as educational attainment and other determinants that have been shown to be strongly related to prejudice, and this reduces their generalizability (Scheepers et al., 2002).

Sociological Studies

Religiosity in sociological studies goes back to dimensions of religiosity (Glock and Stark, 1965; Stark and Glock, 1968): practice, belief, experience, knowledge, and consequences. Most dimensions have been covered in individual publications, although overviews and syntheses are available in some studies (Gorsuch and Aleshire, 1974; Scheepers et al., 2002). In the sociological literature, there is substantial evidence based on large representative national samples that some dimensions of religiosity increase prejudice while other dimensions decrease prejudice, although some scholars find this evidence less conclusive (Ceobanu and Escandell, 2010).

Religious practice relates to denominational membership and church attendance. People considering themselves to be belonging to Christian denominations were rather consistently found to hold prejudices more than nonmembers and members of non-Christian denominations (Scheepers et al., 2002). Lasting controversies on the relationship between church attendance and prejudice have developed, and some contend that the relationship is curvilinear rather than linear. Gorsuch and Aleshire (1974) developed the argument that moderately frequent church attendees were likely to conform to a dominant church culture in which strong sentiments about white supremacy prevail that would induce prejudice; whereas, conversely, nonattendees and frequent attendees were more likely to dissociate themselves from such sentiments that would reduce prejudice. Hood et al. (1996) considered the evidence for the curvilinear relationship not very convincing, and Scheepers et al. (2002) found strong evidence for the linear rather than for the curvilinear nature of the relationship. Before the turn of the century, the more frequent people in European countries attended church meetings, the stronger they supported prejudice. Yet, after the turn of the century, the evidence for a linear relationship seems to have become nonsignificant in many Central and Eastern European countries (Strabac and Listhaug, 2008; Coenders et al., 2009) or even seems to have reversed for anti-immigrant attitudes in general (Bohman and Hjerm, 2013) as well as for anti-Muslim prejudice (Savelkoul et al., 2011).

Regarding religious or doctrinal beliefs, researchers have failed to develop convincing theoretical arguments as to why these beliefs would be related to prejudice: why would substantial beliefs in God be related to prejudice? However, there is clear evidence from many European countries, before and after the turn of the century, that religious doctrinal beliefs reduce prejudice (Scheepers et al., 2002; Bohman and Hjerm, 2013). Yet, there have been overriding arguments as to why another dimension of doctrinal beliefs, i.e., religious particularism, the belief that there is only one true religion, could be related to prejudice (Stark and Glock, 1968). Religious particularism predisposes people to strong religiocentric stances, and induces unfavorable attitudes toward other religions, other religious out-groups, and toward ethnic out-groups that are majority non-Christian. There is strong empirical evidence for this crucial proposition in many European countries: the stronger people support religious particularism, the stronger their prejudice against ethnic minorities (Scheepers et al., 2002).

There are relatively few studies examining the effect of religious experiences and knowledge on prejudice (Hood et al., 1996). However, one recent study using data from several European countries showed that "people with experiences of a spiritual, supernatural nature, may put inner-worldly tensions between in-groups and out-groups into a perspective of mutual tolerance…which would reduce prejudice" (Scheepers et al., 2002: pp. 246–247), However, no studies have examined the impact of religious knowledge on prejudice.

Studies have also related the concept of religious saliency to prejudice (Stark and Glock, 1968), and this sociological concept is strongly related to the psychological dimension of intrinsic religiosity (Allport and Ross, 1967). Those people for whom religiosity serves as a dominant master motive in their daily lives, who take the consequences of their religiosity seriously into account in their daily lives and in their everyday decisions, may be expected to live by one of the commandments to 'love thy neighbor' and consequently be less prejudiced to out-groups. There is strong evidence for this proposition for European countries before the turn of the century (Scheepers et al., 2002).

Just like in the psychological literature, there is also evidence that some relationships between religiosity and intolerance (toward Jews and Muslims) can be explained by authoritarianism (Konig et al., 2000) and, moreover by perceived threat, another intermediary determinant derived from crucial propositions in ethnic competition theories (Savelkoul et al., 2011). And just like in the psychological literature, there are indications that the relationships between religiosity and prejudice have decreased over time. Building on Hall et al. (2010), Bohman and Hjerm report that: "…the strength of the correlation between church attendance and belief and anti-immigration attitudes declines somewhat between the ESS rounds, even though the change is not so dramatic. So, perhaps we have already come to the situation in Europe today, especially in some countries, where we are witnessing a shift in the meaning of being religious…" (2013: p. 12).

Synthesis

Surveying and analyzing the conceptual distinctions and empirical findings of both streams or traditions of research, one tends to conclude that the overall picture has become quite clear as to which dimensions of religion "…make and unmake prejudice…" to rephrase Allport's (1958) paradox. Religious

fundamentalism (reflecting an unquestioning certainty in basic religious truths) focused on in the psychological tradition, is conceptually and operationally akin to the sociological dimension of religious particularism (reflecting the belief that there is only one true religion). Both may tend to encourage (some) religious people to categorize between those living according to these religious truths versus those who do not. There is compelling evidence that those who subscribe to religious fundamentalism, and to particularism, tend to be prejudiced against ethnic minorities. This has been shown to hold for prejudice against ethnic minorities and may also hold for prejudice against religious minorities like Muslims as well as for other (sexual) minorities, who overall deviate more or less strongly from the commandments of their own true religion (van den Akker et al., 2013). From a theoretical perspective, this mere categorization may be related to processes and mechanisms of positive group distinctiveness described in social identity theory (Tajfel, 1982).

Intrinsic religiosity (dominant in religious people for whom religiosity serves as a dominant master motive in their daily lives) is conceptually and operationally akin to the sociological concept of religious saliency (dominant in religious people who take the consequences of their religiosity seriously into account in their daily lives). And compelling evidence shows that these intrinsic orientations seem to promote prosocial orientations and decrease prejudice toward ethnic out-groups. However, there has been no investigation into how intrinsic religiosity or salience might influence prejudice against other groups such as religious and sexual minorities.

From a longitudinal perspective, it seems to have become all the more urgent to focus on changing relationships between dimensions of religiosity, more particularly extrinsic religiosity respectively church attendance, and prejudice against ethnic minorities and migrants. Both psychological and sociological research provides some evidence that these relationships seems to have diminished; however, it is not clear from the empirical evidence what kind of mechanisms are at work. The relationship between church attendance and prejudice may diminish due to different processes: frequent church attendees have over time decreased their prejudices and have become more like non-attendees who have been shown to be less prejudiced or vice versa, nonattendees have over time increased their prejudices and have become more like frequent attendees who have been shown to be more prejudiced. Considering the amount of cross-national, high-quality empirical data available for secondary analyses, these contrasting hypotheses can be tested rigorously in many different countries (http://www.europeansocialsurvey.org/). These data also provide the scientific community with possibilities to test the differential relationships between contextual level religiosity, individual level religiosity, and exclusionist stances toward minorities in their countries. Since many of these European societies have become more diverse in terms of ethnicities, not so many researchers have realized that these countries have simultaneously become more diverse in terms of religiosity: many immigrants consider themselves to belong to other than Christian denominations. In terms of theories on competition on religious markets (Stark and Bainbridge, 1996) as well as in terms of ethnic competition theories (Savelkoul et al., 2011), these demographic changes in the religious landscape need to be urgently tested.

Abstract

With the rise of the comparative sciences in the middle of the nineteenth century, major evolutionary schemes were posited. During the first decades of the twentieth century, these theories were rejected in anthropology, sociology, and the historical sciences. Evolutionary approaches, however, continued in isolation, but grew stronger toward the 1970s. In the historical and social sciences, evolutionary theories gained importance in relation to the Axial Age. The cognitive science of religion, founded in 1990 by scholars of religion, developed hypotheses conceived within evolutionary frameworks. These hypotheses are being tested in the laboratory, in the field, in simulation models, and in the development of historical databases.

Introduction

Religion has generally posed a problem for evolutionary theories. What advantages could beliefs and behaviors that are based on postulated supernatural agents, often with dangerous side-effects and practices, possibly have? What selective advantages have secured the survival of religious behavior ever since the appearance of *Homo sapiens*, behavior that was most likely already in play even before the species arose? Much of the debate on the evolution of religion has been based on what professional scholars of religion critically refer to as the '*sui generis* assumption,' in other words, the assumption that religious behavior is unitive and set apart from all other behaviors, thus requiring special feelings, experiences, brain areas, acts, and, subsequently, special methods for studying it. Contemporary scholarship, on the other hand, understands religion to be a cultural and social phenomenon that can be studied and explained using the same methodologies as in the study of any other social behaviors and institutions. It makes sense, therefore, to study religion within an evolutionary framework.

Religion is understood here as "a cultural system and a social institution that governs and promotes ideal interpretations of existence and ideal praxis with reference to postulated transempirical powers or beings" (Geertz, 1999, p. 471). Religion consists, therefore, of a world of ideas (and/or beliefs) about the natural and supernatural world and about humans and other creatures and beings that inform social behavior and social institutions. It is a powerful instrument that must have had selective advantages. The British scholar of religion, Ninian Smart, has sketched out seven dimensions of religion that may be useful here. Religion, he pointed out, consists of the practical and ritual, the experiential and emotional, the narrative or mythic, the doctrinal and philosophical, the ethical and legal, the social and institutional, and the material dimensions (Smart, 1989, p. 12–21). Religion is obviously a complex phenomenon, and, furthermore, its many dimensions are more or less identical to other cultural institutions as well as secular worldviews (such as nationalism, communism, humanism, and atheism). Religions differ around the world so that some of these dimensions might be missing or downplayed and others overemphasized. There is quite often confusion about religion, not the least, the confusion between religion in the real world and religion as a scientific concept. Religion is as difficult to capture analytically as culture is. And yet, we know that they have causal effects on genes, individuals, societies, and the material and natural world.

Because of the complexity of religious behavior, ideas, and institutions, whole disciplines have arisen dedicated to the scientific study of religion each with their own methods, theories, and perspectives. This has led to a division of labor with the unfortunate side-effect of disciplinary isolation. The professional disciplines dedicated to the science of religion are history of religions (often called comparative religion), the sociology of religion, the psychology of religion, and, quite recently, the cognitive science of religion. Theology and the philosophy of religion have mostly pursued their own a priori interests in theology and belief. Attempts have been and are being made to liberate the philosophy of religion from its (mostly Christian) theological framework. The term "religious studies" is used in the United States and England as a cover term for all of the above.

Early Theories

The nineteenth century was rife with theories about the evolution of religion. For both theological and ideological reasons, most thinkers distinguished between the religions of contemporary indigenous tribes living in the colonies and frontiers of European empires and the religions of 'advanced civilizations,' such as and especially Christianity in its official forms. Darwin followed this practice as well, carefully distinguishing between the social and moral faculties of the "ape-like progenitors of man" and contemporary savage tribes on the one hand and those of "civilized nations" on the other (Darwin, 1874, p. 147–165). Darwin had no doubt that social and moral faculties had selective advantage. But his ideas on religion were clearly based on the discussions and debates among leading intellectuals of the new comparative sciences, such as comparative religion, psychology, sociology, and history, living in the cosmopolitan centers of the empires. Their many schemes and ideas about the evolution of religion were not based on carefully collected data that biologists and geologists were accustomed to. There was no undisputed,

accumulated evidence waiting for a theory that would "transform the obvious" (Wilson, 2008, p. 23). The information they had on religion was being produced in the wilds of the empires, based on interactions often of a violent nature and misunderstandings between uninformed military personnel, colonists, traders, and more or less informed missionaries, on the one hand, and the hapless, highly resistant indigenes on the other (Chidester, 1996). It was not until the introduction of ethnographic fieldwork at the beginning of the twentieth century that the science of culture could begin. Thus, the many evolutionary schemes of the nineteenth century were speculations based on faulty data. Such schemes as those based on comparative religion scholar Friedrich Max Müller's idea that religion arose through enactments of natural phenomena and mythology as a disease of language, comparative religion scholar Sir James George Frazer's theory on the evolution of magic, religion, and science, anthropologist Edward Tylor's theory of the origin of primitive religion in animism, classicist Theodor Mommsen's stages of Roman religious development, sociologist Herbert Spencer's elaborate social evolutionary schemes, beginning with an error of thought, followed by ancestor worship, polytheism and ending with monotheism, sociologist Émile Durkheim's theory of the origin of primitive religion in totemic ritual practices, psychologist Wilhelm Wundt's scheme from errors in causal thinking to various forms of religion, psychologist Sigmund Freud's patricide and the Oedipus complex as the source of religion, jurist Johann Jacob Bachhofen's theory of the primordial matriarchy and its mother goddess worship as the source of religion, and so on, were all more or less rejected during the first decades of the twentieth century. This does not mean, however, that some of their ideas are not useful today.

Theories of the Twentieth Century: Anthropology

Throughout the twentieth century, most scholars in the humanities explicitly rejected evolutionary theory for a variety of reasons. As the accompanying chart indicates, studies on the evolution of religion have only recently (and dramatically) begun to appear (**Figure 1**). Scholars of religion rejected evolutionary theory because of the above-mentioned lack of trustworthy data and also because they were mostly interested in religious texts rather than religious behavior. Most ethnographers under the influence of Franz Boas, Bronislaw Malinowski, and A.R. Radcliffe-Brown had also rejected the evolutionary framework and concentrated their research on intensive, fieldwork-based cultural and social studies of particular groups of people. The common stance for ethnographers and scholars of religion was antitheoretical and dominated by historical and ethnographic particularism.

There were, however, a small group of anthropologists who maintained an evolutionary perspective. Robert L. Carneiro (2003) has provided a useful overview of evolutionism in cultural anthropology. The early stages of the reemergence of evolutionism in the twentieth century were represented especially by Leslie A. White. He argues that the errors of nineteenth-century thinking could not justify the rejection of the concept of cultural evolution. He and other colleagues like him, for instance Alexander Lesser, were a decided minority. After an impassioned talk on the evolutionary approach at the 1939 meeting of the American Anthropological Association before an audience that included Boas himself, White reports that the chair of the session, Ralph Linton, said to him that he would be given "the courtesy extended to suspected horse thieves and shady gamblers in the days of the Wild West,

Figure 1 Graph showing number of articles and books in the Scopus database that contains the terms 'religion' and 'evolution' in title, abstract, or keywords.

namely, to allow them to get out of town before sundown" (White, 1987, p. 14; Carneiro, 2003, p. 101).

Support from other ethnologists who also took cultural evolution seriously grew slowly. These include Julian H. Steward's work on the Great Basin tribes and his editorship of *Handbook of South American Indians* (Washington, 1940–47) which was influenced by the evolutionary paradigms of archaeologists working in Mesoamerica and South America. The British archaeologist V. Gordon Childe with his studies of European prehistory was also crucial in reintroducing cultural evolutionism.

From the 1950s, evolutionary theory began to make an impact on cultural anthropology. Such scholars as Robert Redfield, Kalervo Oberg, Marshall Sahlins, Irving Goldman, and Walter Goldschmidt were all promoting evolutionary approaches in their areas of study. Carneiro notes that 1959, the centennial year of *On the Origin of Species*, was a pivotal point in the return of evolutionary theory in cultural anthropology. He mentions White's book *The Evolution of Culture* (1959) and the Anthropological Society of Washington's collected essays *Evolution in Anthropology: A Centennial Appraisal* (1959). He did not, however, note an equally important collection of essays edited by J.N. Spuhler entitled *The Evolution of Man's Capacity for Culture* (1959). In this latter collection of essays by archaeologists and anthropologists is found an explicit connection between prehistorical archaeology, physical anthropology, and the origins and evolution of culture. That collection furthermore played a profound role in the founding father of symbolic anthropology Clifford Geertz's understanding of culture, evolution, and human psychology.

Not many evolutionary anthropologists were interested in religion. Notable exceptions were neo-Marxists Michael Kearney and Marvin Harris. Kearney's analysis of worldview conceptions among Californian Indians and Mexican peasants is placed within a historical materialist framework (Kearney, 1984). Harris' strident ideology-critical study of the history of anthropological theory is a classic (Harris, 1969), but his smaller collections of essays on such topics as cargo cults, potlatch, messiahs, witch-crazes, and the origin of sacred cows are masterful analyses of religious behavior and ideas within the framework of technological, environmental, and economic development (Harris, 1975, 1977).

The late 1980s and early 1990s witnessed a few signal anthropological studies of religion and evolution. Two warrant special mention. The first, Roy A. Rappaport's *Ritual and Religion in the Making of Humanity* (1999), had a significant impact on a range of disciplines interested in religion. Published posthumously, his complex study argues that religion and especially ritual provided adaptive advantages to humankind and were coextensive with language and culture. For him, the defining characteristic of humanity is that it lives in terms of meanings "it must construct in a world devoid of intrinsic meaning but subject to physical law" (1999, p. 1) and thus he claims that without religion, humanity could never have emerged from its pre- or proto-human condition. Group selection, according to Rappaport, was essential to human evolution. Human systems, he wrote, are "cultural-organic systems constituted by symbolic (linguistic) as well as genetic information" and the "transformation from organic to cultural-organic must have been strongly selected for" (1999, p. 10). The role of religion in nature consists of the relationship between Ultimate Sacred Postulates and the conventional world. He likens this relationship to those of thermodynamics to the physical world (1999, p. 407). He argues that sanctity is significant "both among the adaptive *properties* of the species as a whole and in the adaptive *processes* of the social units into which the species is organized" (1999, p. 414). Sanctity is "the functional replacement for genetic determination of patterns of behavior" (1999, p. 418) because it "forms an unchanging ground upon which all else in adaptive social structures can change continuously without loss of orderliness" (1999, p. 427). In this sense, religions are cybernetic systems.

Rappaport's impact on the humanities consisted more of his analysis concerning the nature of religion and the logical, social, and subjective effects of ritual (which concerns the bulk of the book) rather than the adaptive role that religion played in the emergence of humanity. Even at this late date, the majority of researchers in the humanities and some social scientists were still "evolution-blind" mostly for ideological reasons. The anthropological-sociological team of Jonathan H. Turner and Alexandra Maryanski spelled out more specifically in their book *On the Origin of Societies by Natural Selection* (2008) what social evolution consists of. Their goal is to make the relationship between "human biology and sociocultural arrangements more explicit and systematic by exploring the ways that biology, social structure, and culture interact" (2008, p. 2). They posit five forces of the social universe that generate selection pressures: population, production, distribution, regulation, and reproduction (2008, p. 125). These forces are systematically analyzed in terms of sociocultural systems: hunter-gatherer, horticultural, agrarian, industrial, and postindustrial societies. Emphasis is placed on the ecology, demography, economy, kinship system, religion, polity systems, social institutions, and stratification systems of each social type. The result is a finely detailed analysis of the role that religion and ritual has played in interplay with the other selective forces. Thus, in this very hands-on approach, Turner and Maryanski have produced a highly readable application of evolutionary theory for cultural scientists. Their argument is clear: "we … need to be attuned to the fact that human biology not only makes human culture and social structure possible …, but the viability of culture and social structure over the long term is affected by the biology of humans as an evolved primate" (2008, p. 2).

Theories of the Twentieth Century: Sociology

Sociologists, with their interest in social structures and institutions, have a strong evolutionary tradition. All of the nineteenth and early twentieth century sociological thinkers assumed evolutionary schemata, such as August Comte's law of history, Herbert Spencer's detailed evolutionary scheme, Lewis H. Morgan's technology-driven evolutionary eras, the historical materialism of Karl Marx and Friedrich Engels, Max Weber's individual drive for domination and control, and Émile Durkheim's theory of the mechanical and organic solidarity and the division of labor. Sociologists also experienced an antievolutionary movement, and according to Pierre L. van den Berghe still were in 1990: "Sociological resistance to biological

thinking is in large part *trained* incompetence, not simply garden-variety anthropocentrism" (Berghe, 1990, p. 177).

Talcott Parsons' work on social evolution came to have an influence on mid-twentieth century and later sociology. Talcott Parsons completed his PhD and Dr Phil in Heidelberg and was therefore exposed not only to Karl Jaspers but also to Alfred Weber (Max Weber's brother), Edgar Salin, Emil Lederer, Karl Mannheim, and Ernst D. Troeltsch. Especially with the founding of the Department of Social Relations at Harvard, which was an institutional attempt to bring psychologists, sociologists, and anthropologists together, Parsons had a profound influence on many scholars such as Robert K. Merton, Clifford Geertz, Harold Garfinkel, and Robert N. Bellah. In developing his systems theory, Parsons was influenced by Alfred Emerson's idea that the symbol was the functional equivalent of the gene. Parsons envisioned three stages of evolution: the primitive, archaic, and modern.

Of the sociologists who have made an impact on the study of religion within an evolutionary perspective, Robert N. Bellah warrants special mention. He and Parsons had known each other for many years and had regularly corresponded. Already in 1964, Bellah introduced his theory of social evolution in the *American Sociological Review* which was largely ignored. It was based on ideas presented during a seminar on social evolution which Bellah gave together with Talcott Parsons and S.N. Eisenstadt at Harvard University in the spring of 1963 (Bellah, 1964, p. 358). In an earlier essay on Durkheim and history, Bellah emphasized, "I agree with Durkheim that the problem of evolution, including even social origins, is central for sociology as a science. To be convincing, this view must be backed by research – a challenge not to be evaded" (1959, p. 460 n.62).

The prime exponent of the analytical turn in comparative religion, Jonathan Z. Smith, remarked on Bellah's article in one of his publications that it was "irresponsibly crude" (Smith, 1987, p. 52). Smith was not against evolutionary theory, but he was concerned that the article did not specify mechanisms or carriers of evolution. Fortunately, Bellah took on the topic once again, and partially met the challenge raised in his 1959 article by publishing shortly before his death in 2013 a monumental study entitled *Religion in Human Evolution: From the Paleolithic to the Axial Age* (2011). Smith subsequently acknowledged Bellah's achievement at a panel during the American Academy of Religion 2011 annual meeting. In an unpublished but widely circulated, handwritten copy of his paper, Smith retracted his previous criticisms and noted that "the burdens of mechanism, agency, bearer et al. now fall to the biological. It is the genus *Homo* and not generic 'religion' that is the subject of evolution" (Smith, 2011, p. 4).

Smith was not entirely correct in his initial characterization of Bellah's earlier paper. Having been influenced by Parsons' systems theory, the mechanisms undergoing evolution according to Bellah are systems, whether human, animal, bacterial, or any other systems, persisting through time and adapting to change. The abstract to his article explains his understanding of evolution:

> Evolution in the sphere of religion is traced on three levels. First and most central is the evolution of religious symbol systems which are described as moving from "compact" to "differentiated." In close conjunction with this evolution, religious collectivities become more differentiated from other social structures and there is an increasing consciousness of the self as a religious subject. Five ideal typical stages of development are posited but it is recognized that these stages are not inevitable, that there is a wide variety of types within each stage, and that actual cases present many important features which cannot be neatly characterized in terms of any one stage. The close connection between religious evolution and other aspects of socio-cultural evolution is assumed but not explored.
>
> Bellah, 1964, p. 358

Thus, Bellah's interest is in the evolution of symbol systems. In his opus, that interest has not changed. His vision, however, did. Smith was correct in that evolution for Bellah "is part of the human story all the way through, though quite a long time ago it gave rise to culture and has coevolved with it ever since" (Bellah, 2011, p. xi). Bellah's story literally begins with the Big Bang (2011, p. 50ff.), but his abiding interest is still in symbol systems and in the way that religion shapes the social order and everyday life. Bellah draws on psychologist Merlin Donald's three evolutionary stages of human culture: mimetic, mythic, and theoretic that occurred during the past 2 million years (Donald, 1991, 2001). All of the phases presuppose the subsequent phases and are still present in those phases: Bellah's maxim here is "Nothing is ever lost" (Bellah, 2005, p. 72). The phases of mimetic and mythic are evident in tribal religions. As societies became more complex, chiefdoms and kingships arose in the archaic phase with hierarchical social classes supported by myth and ritual pageantry. During the first millennium BCE, theoretic culture appears giving rise to the critical questioning of the old myths and sterile ritualism of earlier forms. These cultures and their religions, Buddhism, Ancient Greece, China, Judaism, and India, during the so-called axial age, promote an ethical and spiritual universalism (2011, p. xix). Bellah's book consists of an erudite fleshing out of these three phases: Tribal, Archaic, and Axial. As he notes in the introduction, his book ends where the last 2000 years begin. So the last two of the original five phases that he sketched out in his 1964 article were left untouched: Primitive, Archaic, Historic, Early Modern, and Modern. But others in the history of religions have picked up where Bellah left off.

Theories of the Twentieth Century: Comparative Religion

As mentioned, most scholars in the humanities, including historians of religion, explicitly rejected evolutionary theory. The common stance in comparative religion was historical and ethnographic particularism. For decades, there was a struggle between particularism and the broader more theoretical need for comparativism. Evolutionary theory, however, had no place in this struggle. As Robert Bellah opined in the above-mentioned 1964 article:

> … by the third decade of the 20th century the evolutionary wave was in full retreat both in the general field of science of religion and in the sociology of religion in particular. Of course, this was only one aspect of the general retreat of evolutionary thought in social science,

> but nowhere did the retreat go further nor the intensity of the opposition to evolution go deeper than in the field of religion.
>
> Bellah, 1964, p. 358

There were, however, a few scholars who were not anti-evolutionists. One warrants mention here, namely the German Egyptologist Jan Assmann.

The term 'axial age' ('Achsenzeit,' i.e., 'axial period') is widely held to have been introduced by the German existentialist philosopher Karl Jaspers in his book *Vom Ursprung und Ziel der Geschichte* ["On the Origin and Goal of History"] (1949). Hans Joas, however, has pointed out that Georg Simmel in his *Lebensanschauung* (1918) used the term axis before Jaspers, although Jaspers does not refer to him. Jaspers developed his ideas in dialogue with and against Hegel, but was most likely influenced by Max Weber, his brother Alfred Weber, and their colleagues Ernst Troeltsch and Wilhelm Bousset. They were in turn influenced by the historian of religions Hermann Siebeck and indologist T.W. Rhys Davids, so, Joas notes, "one could already speak of an 'Axial Age debate' around 1900" (Joas, 2012, p. 11). But they were not the first ones. Jaspers mentions sinologist Victor von Strauss and classicist and philosopher Ernst von Lasaulx. Lasaulx, on the other hand, mentioned Abraham-Hyacinth Anquetil-Duperron (1731–1805) as a forerunner. The founding father of Iranian studies, Anquetil-Duperron claimed in 1771 that Zoroaster's religious ideas in the sixth century BCE were a part of "a more general 'revolution' in different parts of the world" (Joas, 2012, p. 11).

The term was meant to cover the major religious and philosophical movements in the first millennium BCE throughout Eurasia. Jaspers did not look for the material conditions behind these independent movements, but posited a spiritual change that was independent of social and material conditions. This claim was closely bound to his ethical, political, and philosophical attempts to formulate a postwar philosophy of history. Bellah, Shwartz, and Eisenstadt, however, brought the term into the realms of natural history. Whereas Bellah focused more on the moral and practical dimensions of the axial age and the effects that it had on human cognition, sociologist Eisenstadt was concerned with the role that intellectuals had in the transformation. His understanding of the term was that axial age civilizations were a type of social order and thus not necessarily bound to an actual historical time period. This approach – which Eisenstadt promoted through a series of conferences with subsequent influential publications (1986, 1987, 1992) – brought Christianity and Islam into the picture (Boy and Torpey, 2013, p. 253). It should be noted, however, that Eisenstadt was convinced that the rise of Axial civilizations was a revolutionary rather than an evolutionary process (reiterated in Eisenstadt, 2012, p. 277). This was because of the social disruption that characterized all of the Axial civilizations.

As John D. Boy and John Torpey note in their detailed history of the term:

> The full-blown shift to a notion of "axiality" emancipated from the specific epoch delineated by Jaspers comes in two variants: that seeking to move "axiality" to an earlier time period, and that seeing it as an occasional phenomenon in human history with no prescribed temporal coordinates whatsoever.
>
> Boy and Torpey, 2013, p. 253

Eisenstadt represents the latter, whereas Jan Assmann's work clearly represents the former. Jan Assmann was a professor of Egyptology in Heidelberg. He is especially important because he consistently placed his work in relation to broader cultural theories and to cultural evolution. He understood the cultural evolution of religion to consist of the transition from 'primary religions' to 'secondary religions'; in other words, from cultures totally immersed in religious worlds to cultures in which religious worlds were relative to one another and could therefore be the objects of individual choice. The latter distinction led to the idea of 'true' and 'false' religions and the consequent idea of sanctions against those who hold the false religions. Assmann considered Egyptian religion as an example of a primary religion and Israelite religion as an example of a secondary religion, also characterized by Assmann – rightly or wrongly – as the transition from polytheism to monotheism (Assmann, 2003). In relation to the Axial debate, Assmann argued that the transition already occurred with the invention of writing (especially the culture of writing) and thus pushed axiality further back in history.

Furthermore, Assmann takes issue with Jaspers' understanding of preaxial and postaxial worlds. Through an analysis of the Egyptian term *ma'at*, 'truth, order, justice,' Assmann argues that the breakthrough of transcendence, which Jaspers considered to be characteristic of the Axial Age, was already represented in Ancient Egypt (Assmann, 1990, p. 121). In his contribution to the anthology on the Axial Age, edited by Bellah and Joas, Assmann argued that the Axial Age is "a creation of philosophers and sociologists, not of historians and philologists," in the sense that the latter are concerned with the past as far as it can be discerned whereas the former are concerned with the roots of modernity. He calls this attempt the quest for beginnings and in this sense exhibiting mythical qualities. "Myths," he argues, "tend to construct beginnings" (Assmann, 2012, p. 366). Assmann's criticism is well-placed and needed, although he is not the only friendly critic of the Axial debate. He rightly points out that the debate began during transitional periods in the nineteenth-century paradigm of progressive evolution and re-invoked in the social upheavals of twentieth-century Europe (2012, p. 369). This should give pause for thought. Assmann is not against the idea of cultural evolution. He simply points out that cultural evolution also involves conscious processes and manipulations by the populations undergoing cultural change (Assmann, 2012, p. 368).

The Axial Age debate is important because it is perhaps the main hypothesis that has succeeded in bringing historians of religions and other historians more or less directly into evolutionary theory. Furthermore, new developments in quantitative approaches to history have targeted, among others, the Axial Age hypothesis as worthy of testing. As will be mentioned below, zoologist Peter Turchin, biologist David Sloan Wilson, and cognitive scientists of religion Harvey Whitehouse and Edward Slingerland are all involved in developing world history databases that can serve as quantitative testing grounds of the historical evidence.

Theories of the Twentieth Century: The Cognitive Science of Religion

Although the cognitive science of religion (CSR) grew out of religious studies, it was also significantly influenced by psychology. It should be noted, however, that it was not general psychology, but a specific branch of the field, namely, evolutionary psychology, that influenced the early phases of the CSR.

As with all of the main sciences mentioned here, history, sociology, comparative religion, and so on, scientific psychology arose with Wilhelm Wundt in Leipzig during the Darwinian revolution of the latter decades of the nineteenth century. It was clearly also the inheritor of the many philosophies of mind prior to that century (Hume, Descartes, Aristotle, and so on). As Plotkin notes in his brief history of evolutionary theory in psychology, the difference between the new psychology and former philosophies of mind was an interest in psycho-physiology and the possibility of quantifying mental phenomena (Plotkin, 2004, p. 29). Wundt, however, also envisioned a supplement to his experimental psychology which was concerned with cultural factors and was like cultural anthropology. He had a significant impact on almost all the main intellectuals of the time – especially Americans (psychologists such as William James, Stanley Hall, Edwin Starbuck, and James Leuba). Sigmund Freud, despite the problems with his theory and methods, situated his ideas within the framework of evolutionary theory (Plotkin, 2004, p. 33). William James, the founder of American psychology, conceived of human psychology in his two-volume *Principles of Psychology* (1890) within the framework of Darwinian theory. However, neither James nor other later influential psychologists, such as John Dewey and B.F. Skinner, actually used evolutionary theory as an analytical tool in empirical studies (Plotkin, 2004, p. 46–47). An exception was James Mark Baldwin who, unfortunately, plagued by scandal, was forced to retire from his academic positions and left the United States. Plotkin argues that Baldwin was a 'real' evolutionary psychologist, that he had an impact on evolutionary theory, that he discovered cognitive developmental stages in humans, that he arguably anticipated the Theory of Mind, and that he contributed significantly to evolutionary epistemology (Plotkin, 2004, p. 70). He preceded by decades the theories of Jean Piaget and Lev Vygotsky. Behaviorism drastically changed the American scene. Although it represented the triumph of empiricism, "Nurture and blank slates ruled, evolution was gone, and so too was the rationalism of Plato and Descartes" (Plotkin, 2004, p. 62).

The cognitive revolution of the 1950s changed all of that especially under the influence of linguist Noam Chomsky along with the other fathers of the revolution, namely George Miller, Johan McCarthy, Marvin Minsky, Allen Newell, and Herbert Simon. Although the break with behaviorism allowed the scientific study of the mind, the main paradigm was of course the mind as an information processor. As philosopher Paul Thagard has shown in his history of the cognitive sciences, there are six competing, independent intellectual traditions that have so far failed to produce a unified theory of mind (Thagard, 1996, p. 128).

The real breakthrough in the sciences of the mind came in the late 1980s with the founding of evolutionary psychology out of the ashes of sociobiology. The latter was an attempt at applying animal ethology to human behavior, most spectacularly demonstrated in biologist Edward O. Wilson's *Sociobiology: The New Synthesis* (1975). As Kevin N. Laland and Gillian R. Brown note in their research history of evolutionary perspectives on human behavior, Wilson's book opened "a land rush of biologists into the territory of the human sciences, where they received an extremely hostile reception" (Laland and Brown, 2002, p. 71). This hostility, however, brought a well-deserved backlash most persuasively led by the founders of the first Center for Research in Evolutionary Psychology, anthropologist John Tooby and psychologist Leda Cosmides. Tooby and Cosmides formulated their thesis in direct opposition to what they polemically called the Standard Social Science Model (SSSM). They posit what they call the Integrated Causal Model (ICM). In their groundbreaking chapter in *The Adapted Mind* (1992), Tooby and Cosmides argued that the cognitive tasks in what they termed the "environment of evolutionary adaptedness (EEA)," roughly covering the stone age, could not have been dealt with through socialization processes. Our ability to adapt to the challenges of the environment was ensured by genetically evolved domain-specific modules. They thus rejected the idea that the brain is a domain-general learning mechanism. In their view:

> … culture is the manufactured product of evolved psychological mechanisms situated in individuals living in groups. Culture and human social behavior is complexly variable, but not because the human mind is a social product, a blank slate, or an externally programmed general-purpose computer, lacking a richly defined evolved structure. Instead, human culture and social behavior is richly variable because it is generated by an incredibly intricate, contingent set of functional programs that use and process information from the world, including information that is provided both intentionally and unintentionally by other human beings.
>
> Tooby and Cosmides, 1992, p. 24

Although they succeeded in bringing the mind back into evolutionary theory, their adamant modularity has been criticized by many, and Laland and Brown argue that evolutionary psychologists should pay more attention to evolutionary biologists who have developed rigorous methods for analyzing evolutionary processes (Laland and Brown, 2002, p. 194).

Tooby and Cosmides were not interested in religion, but they had a decided impact on the cognitive science of religion. In fact, the first to consciously formulate the new cognitive science of religion, scholars of religion E. Thomas Lawson and Robert N. McCauley (1990), did so as an alternative to the dominant, mostly postmodern and antiscience, cultural studies that also came to dominate religious studies first in the United States and later in Europe. Attempts by historian of religions Jonathan Z. Smith to transform religious studies to an analytical and critical endeavor during the 1970s and 1980s foreshadowed the birth of the cognitive science of religion, although Smith himself never dealt with the topic of cognition except to say that "the burgeoning enterprise of cognitive theories of religion has begun to provide theoretically interesting and important empirical observations toward an evolutionary account of

religion…[but] not having yet fully mastered the relevant literature has prevented me from doing much more, in public speech, than calling attention to this development and signaling my interest in it" (Smith, 2011, p. 3).

There were precedents to the CSR of course. One of the most obvious was anthropologist Stewart Guthrie's groundbreaking 1980 article "A Cognitive Theory of Religion" which was published in the prestigious anthropological journal *Current Anthropology*. It was published as a target article with peer response. In it, Guthrie argues that "religious and nonreligious belief and behavior can best be understood as closely related variants of a single human cognitive process, not as polar opposites" (Guthrie, 1980, p. 181), a statement addressed to the rationality debate at the time and not to evolutionary theory. He was also mainly concerned with defining religion. His main hypothesis, however, which he developed in a major book 13 years later (1993) is that religion is a form of anthropomorphization. This hypothesis has been widely acknowledged as a key contribution to an evolutionary theory of religion. The gist of the hypothesis is that religion is "systematic anthropomorphism: the attribution of human characteristics to nonhuman things or events" (1993, p. 3). The strategy of attributing human like characteristics to nature helps us navigate in an uncertain world. Even though we often err, the times we are right more than justify the strategy in terms of survival. Thus, Guthrie's theory is both a cognitive and an evolutionary one. Guthrie draws on cognitive theories of perception which indicate that perception is predisposed to anthropomorphism. Although he formalizes his theory in terms of five propositions and two informal deductions, Guthrie does not systematically explore anthropomorphism in terms of evolutionary theory. He does, however, state our capacity for anthropomorphization is built in: "not mere opportune exploitation of anatomy and neurology, but a biologically broadly based, deeply integrated system" (1980, p. 189). The challenge of formulating his hypothesis in evolutionary terms was later taken up by psychologist Justin Barrett.

Barrett performed tests with Frank C. Keil on university students' tendency to anthropomorphize in their concepts of God (Barrett and Keil, 1996). Later, he postulated a cognitive mechanism he termed 'hyperactive agency detection device' (HADD) which he claims is an essential element in the origin of religious thought, more specifically, belief in supernatural beings (systematically argued in his popularized book *Why Would Anyone Believe in God?*, 2004). By device, he means evolved, specialized mental tools in the brain that help us survive in the world. He argues that these tools consist of categorizers, describers, and facilitators. The categorizers consist of among other things an agency detection device. Among describers, one finds Theory of Mind (ToM), the ability to attribute mental states to other people. These two in combination are essential to the evolution of God beliefs. Three facilitators are also essential to the development of religious beliefs, namely, social exchange regulator, social status monitor, and intuitive morality (Barrett, 2004, p. 3–5). Barrett is agnostic about whether these mental tools are hardwired in the brain and thus leaves open the question of whether these tools really are evolutionary adaptations.

Lawson and McCauley formulated their dissatisfaction with cultural studies by arguing that their approach is explanatory rather than interpretive. Without regard to cognitive constraints, they argue, interpretations will be misguided. Drawing inspiration from the competence approach in linguistics (Chomsky), they claim that participants' representations of ritual acts constrain both the form and types of acceptable ritual behavior in a given religious system (Lawson and McCauley, 1990, p. 8; 78). Their theory has three major components: (1) an action representation system, (2) a religious conceptual scheme, and (3) universal principles of religious ritual structure (1990, p. 121). Rituals are thus analyzed much along the same lines as in generative linguistics. The universal principles, they argue, are the core of their theory and "offer some basis for formulating a genuine explanation of these phenomena" (1990, p. 121). Although they are simply postulated, the principles hinge on their action representation model. The first principle is the Principle of Superhuman Agency and the second is the Principle of Superhuman Immediacy. Their proximity and position in ritual action determines particular types of rituals (1990, p. 125). Lawson and McCauley do not specifically address evolutionary issues.

In a second book, which is mostly concerned with Harvey Whitehouse's modes of religiosity hypothesis, they add the further elements of sensory pageantry, memory, and motivation to their ritual form hypothesis in order to reveal "larger patterns in the evolution of religious ritual systems…that cut across cultures and historical epochs" (McCauley and Lawson, 2002, p. 7). Their goal is to delineate "the cognitive architecture of *Homo religiosus* – not merely to understand well-known historic patterns in religious systems better but also to *explain* them" (McCauley and Lawson, 2002, p. 8). But they are more specific in relating their model to evolutionary theory. Especially in terms of memory, their interest is on what psychological mechanisms ensure the faithful transmission of religious and ritual representations across generations. They argue:

> … if religious systems, in fact, evolve in the direction of greater memorability, at least in the absence of special cultural tools for the faithful preservation of such representations, then the relevance of these matters to the transmission of religious ritual should be clear …. [M]ost religious systems, including all of the great world religions, emerged among populations that were mostly illiterate…. Thus, it should come as no surprise that religious systems and ritual systems, in particular, have evolved so as to exploit variables that facilitate memory.
>
> McCauley and Lawson, 2002, p. 85

These issues are systematically explored in their analyses of the evolution of particular rituals and religious systems in New Guinea.

The issue of memorability is the main point of departure for the other founding father of CSR, anthropologist Pascal Boyer. Already in his earliest volume, *Tradition as Truth and Communication* (1990), Boyer argues that anthropology needs a strong psychological theory if it wishes to explain tradition. He rejects the usual explanations of socialization, cultural models, and/or meaningful symbols so common in anthropological research. Instead, he posits in his 1994 book *The Naturalness of Religious Ideas* that the success of religious

ideas is that they are well-formed in terms of evolved cognitive domains or repertoires, which he later termed 'templates' in his 2001 book *Religion Explained*. In this sense, religious ideas are natural. He notes that religious ideas have three features: they contain counterintuitive claims, inscrutable concepts and inferential gaps (1994, p. 53). Thus religious ideas build upon and use normal cognitive domains. These domains supply information intuitively and effortlessly. Inference systems, he notes, direct our knowledge acquisition and assist us in surviving in our environments. To this more or less ready information is added a slight tweak or counterintuitive property, such as tigers that fly, statues that listen, or humans that rise from the dead, which make the property cognitively salient and thus more easily remembered and passed on. Boyer neatly sums up what has become the standard understanding of religion by CSR scholars:

> (1) Most of the relevant mental machinery is not consciously accessible. People's explicitly held, consciously accessible beliefs, as in other domains of cognition, only represent a fragment of the relevant processes. Experimental tests show that people's actual religious concepts often diverge from what they believe they believe. This is why theologies, explicit dogmas, scholarly interpretations of religion cannot be taken as a reliable description of either the contents or the causes of people's beliefs; (2) What makes religious thoughts 'natural' might be the operation of a whole collection of distinct mental systems rather than a unique, specific process; (3) In each of these systems religious thoughts are not a dramatic departure from, but a predictable by-product of, ordinary cognitive function.
>
> Boyer, 2003, p. 119

Thus, the by-product argument came to influence the burgeoning new cognitive science of religion. This has become a point of disagreement in relation to later approaches. It should be noted that Boyer recently has developed a more sophisticated argument concerning religious ideas based on experimental evidence. Thus he argues in his article "Functional Origins of Religious Concepts" (2000) that religious ideas are not solely salient because of their counterintuitive properties. This is the so-called "Mickey Mouse problem": not all counterintuitive agents are religiously salient. Those agents that are religiously salient are connected to morality, group identity, ritual, and emotion, and, furthermore, have perfect access to socially strategic information. The mental mechanisms that our evolutionary heritage has given to social interaction are a hypertrophy of social intelligence, a capacity to evaluate potential cooperators and to detect potential defectors, a repertoire of moral feelings, the stability of some unfakeable (or difficult to fake) signals, easily produced self-deception, and emotional rewards for gossip (Boyer, 2000, p. 203–204).

As noted above, most cognitive scientists of religion accepted the computer metaphor of the mind and rejected any causal influence that culture might have on cognition (Geertz, 2004, 2010b). Furthermore, they assume all religious thought and behavior to be by-products of naturally selected cognitive mechanisms. Others take issue with this assumption. Anything as costly as religious behavior must have had selective advantages, if not on an individual level, surely on a group level. Furthermore, the interrelations between cognition and culture are mutual. The whole area of epigenesis is currently being explored by many biologists, philosophers, and others who point out that the relations between genes and culture are not at all as clear-cut as has been assumed (Richerson and Boyd, 2005; Tomasello, 1999). Sociocultural anthropologist Benjamin Purzycki and behavioral ecologist Richard Sosis succinctly stated:

> … religion is a transsomatic adaptation. At the genic level, the religious system constitutes an extended phenotype that has been fashioned by natural selection to overcome socioecological challenges inherent in human sociality, primarily problems of cooperation and coordination. At the collective level, the religious system constitutes a cognitive niche.
>
> Purzycki and Sosis, 2013, p. 99

As a historian of religion, I have argued that we need to push further back into our evolutionary sapient history in order to understand the origins of religion. I have long argued that culture and cognition became so closely meshed, even before the appearance of *Homo sapiens* that clear-cut causal relations are almost impossible to distinguish in both natural and experimental contexts. It seems fairly certain that tool-making was one of the prime causal mechanisms behind the expansion of the brain and other physiological changes in the hominin line. Fire control and cooking were most likely also contributing factors to the development of our cognitive abilities. The use of symbolic objects and possible symbolic behavior seems to be fairly ancient, most likely during the time of *Homo erectus*. The kinds of minds we must look for in the archaeological record would have a finely honed social cognition, a drive to communicate and cooperate, a self-deceptive brain, and a superstitious brain prone to unusual mental and/or emotional experiences (Geertz, 2013, p. 31). These characteristics are based on recent neurological and neuropsychological insights. Brains are prediction organs busily constructing the world in order to help us negotiate and survive in natural, social, and psychological environments. They are creative organs, filling in all of the missing data in the sensed world. One side effect, however, is that they are also highly vulnerable to influence when manipulated in specific ways. I therefore argue:

> We are intelligent apes that are highly emotional, easily spooked, very superstitious, extremely sensitive to social norms and virtual realities, and equipped with nervous systems that are vulnerable to influence from conspecifics and their symbolic worlds. These traits are prerequisites for religious behaviour.
>
> Geertz, 2013, p. 19

Religious behavior would have evolved gradually, but it evolved with an evolving brain that evolved in particular ways, especially in the prefrontal cortex where the executive functions developed. Planning, conscious deliberation, identity, self-reflection, and communication are all closely interwoven in these areas. And they coevolved with culture. Thus, the result is

that we are biocultural creatures (drawing on Merlin Donald; Geertz, 2010a) that are born unfinished but ready to adapt to the cultural environment within which the brain grows and matures. Our brains are helpless without cultural frameworks, role models, norms and rules as well as an intense interaction of feeling felt by emotional conspecifics (Siegel, 2001; Turner and Maryanski, 2008). Religion, like other cultural traits, would thus have a selective advantage for such brains.

One of the more robust adaptive hypotheses was developed by Richard Sosis and scholar of religion Joseph Bulbulia. Drawing on the costly signaling theory of Amotz Zahavi and Avishag Zahavi, Sosis and Bulbulia argue that religious behavior can be defined as "a costly signal capable of authenticating religious commitment" (Bulbulia, 2004, p. 669). In a comparative study of 200 religious and secular communities in nineteenth-century United States, Sosis found that religious communities lasted four times longer than secular ones even though they imposed twice as many costs (Sosis, 2000; Sosis and Bressler, 2003). The use of such signals seems to solve the problems of establishing trust among strangers, detecting free-riders and defectors, and generally providing a means of predicting behavior: "We believe that cultural evolutionary scholars are correct to notice…that norms evolve to manage problems of cooperative prediction among strangers, the solution of which is a condition for the possibility of cooperation in large social worlds" (Bulbulia and Sosis, 2011, p. 373–374).

A variant of this hypothesis, proposed by anthropologist Joseph Henrich, concerns learners' prestige-bias. The hypothesis is that learners have "evolved to attend to *credibility enhancing displays* (CREDS)" that "provide the learner with reliable measures of the model's actual degree of commitment to (or belief in) the representations that he has inexpensively expressed symbolically (e.g., verbally)" (Henrich, 2009, p. 244–245). In this sense, CREDs are cultural immune systems that have spread by cultural group selection.

One of the problems confronting cognitive scientists of religion is the inability to test their evolutionary hypotheses. Since quantifiable historical data are either lacking or are of questionable quality, the only other option is to perform psychological experiments in the laboratory or in the field. The logic is that if psychological tests can demonstrate intuitive responses from participants, then it is likely that the responses are universal traits, constraints, mechanisms, and so on, that again, most likely, were selected for during our evolution. Since most of the participants are Western, Educated, Industrialized, Rich, and Democratic (dubbed WEIRD by Henrich et al., 2010), it is surprising that psychologists haven't been more self-critical. Fortunately, cross-cultural studies are being performed, but a large number of them consist of self-report surveys, which of course is almost as problematic. Then there is the whole problem of priming (Bargh, 2006; Doyen et al., 2012) and, finally, the most worrying tendency of skipping replication (or ignoring nonreplication) and accepting 'consensus' as a kind of fact. These are not weaknesses affecting the CSR in particular. It is a general problem in experimental psychology and in social priming (Kahneman, 2012). CSR scholars are, however, plagued by these problems as well.

There is a growing number of articles claiming support, or not, of the main CSR hypotheses. One obvious candidate for testing is the claim that religions, and especially religious rituals, promote prosociality. Realizing that the CSR has mostly remained on a metatheoretical level, younger generations have become quite adept at designing psychological experiments, computer simulations, and field experiments. Various teams have performed field experiments among people who use firewalking and/or piercing rituals. The main hypotheses that have been tested concern whether extreme rituals promote prosociality and solidarity (Konvalinka et al., 2011; Xygalatas et al., 2013a; Fischer et al., 2013), whether extreme rituals stimulate episodic memory (Xygalatas et al., 2013b), and whether rhythm and synchrony promote prosociality (Cohen et al., 2010; Reddish et al., 2014). All of these hypotheses are well-known in the science of religion literature and in psychological literature.

In their review article, scholars of religion Panagiotis Mitkidis and Gabriel Levy have shown, however, that the evidence on whether religion promotes prosociality is contradictory and some of the positive results may be due to other factors. Studies showing that religious individuals are more altruistic, generous, cooperative, etc. are plagued by limitations and biases. Survey and correlational studies are often inadequate in determining causality or in identifying confounding factors. Self-report studies may be influenced by participants' social desirability biases. They argue that "despite the occasional study that has shown a weak or ambiguous correlation between aspects of religiosity and (actual) prosocial behavior…, the bulk of the evidence suggests that such a correlation is absent … or even negative" (Mitkidis and Levy, 2014, p. 3–4). Neither religion nor religious rituals promote prosociality on their own. Religious institutions have, however, organized "a matrix of other actions and exposures that do promote prosociality" and bring people into situations exposing them to effective primes (Mitkidis and Levy, 2014, p. 6). An example of the latter is the use of eyes, whether in paintings, icons, images, or symbols. The experimental evidence indicates that the mere presence of eyes or eye-like symbols affect participants' behavior (e.g., Haley and Fessler, 2006). They conclude:

> In other words, in our understanding religion is not a powerful social force so much because of what it does but because of what people think it does. Religion is a set of institutionalized attitudes (such as beliefs) and practices organized around one or more superhuman agents and branded as a guarantee of moral norms. Religious institutions surround themselves with priming technologies that often produce prosociality – they attempt to monopolize these technologies – but religions are in no way the only institutions that do so. In this sense, any particular prosociality due to religion is more of an accident than a product of design.

Another strong candidate for an evolutionary hypothesis is that religious behavior promotes better health. This area, however, is particularly plagued with faulty designs and overblown conclusions. A recent study has shown that prayer does not relieve pain physiologically. Religious participants, however, self-report a subjective reduction in pain intensity and pain unpleasantness (Jegindø et al., 2013a). A follow-up

test using fMRI technology repeated the results despite the fact that some of the religious participants were administered naloxone, an opioid-blockage medicine (Jegindø et al., in review). In extreme rituals, performed on Mauritius, the team found that dissociation experienced during the rituals were effective ways of coping with the pain (Jegindø et al., 2013b). The fact that placebo may be at play is another example of how religious institutions may have benefited by manipulating expectations and biological mechanisms (Tracey, 2010; Vase et al., 2009, 2011). Despite claims of a consensus on the positive effects of religious behavior and belief on health (for instance Koenig et al., 2001; see critique of the field by Sloan, 2006), the most one can claim is that religious behavior may help patients cope with their afflictions (Pargament, 1997). Even meditation studies and mindfulness studies are inconclusive (Cahn and Polich, 2006; Goyal et al., 2014). There is no doubt that religious institutions have throughout history dealt with health, illness, and death. But again, these institutions have learned to use endogenous mechanisms already in place.

A promising development in testing evolutionary hypotheses of religion is the use of simulations and databases. Examples of the use of simulations to test hypotheses is well-known in biology but not in the humanities (Nielbo et al., 2012). Anthropologist Harvey Whitehouse has attempted to use these new tools in testing his modes of religiosity hypothesis (2000; 2004). Briefly, Whitehouse hypothesizes that the dichotomy of religious experience (i.e., the ecstatic and the more mundane) often noted by scholars of religion can be explained in terms of why people remember their beliefs and rituals and why they are motivated to pass them on. The two types of religiosity, which he calls the doctrinal and the imagistic modes of religiosity, are caused by the ritual stimulation of semantic memory for the former and episodic memory for the latter. Thus, in the doctrinal mode, frequent repetition activates semantic memory for religious teachings and implicit memory for religious rituals. This type of religiosity is usually found in large, anonymous communities led by centralized religious leadership. In the imagistic mode, on the other hand, infrequent repetition accompanied by high arousal activates episodic memory. Since such religious behavior is normally localized in small groups without centralized leadership, the individual is moved by his or her own spontaneous reflections, thus leading to a diversity of religious representations. The modes theory posits psychological causes of sociopolitical features (2002, p. 308–309). Because such features are long term and involve larger social dynamics, testing the theory is a formidable problem. Thus there is a need for simulations and large-scale databases.

Whitehouse has been at the forefront of pursuing both types of testing which is concurrent with developments in quantitative and experimental approaches to history. In using simulations, Whitehouse discovered aspects in the modes theory that were underspecified, thus generating new hypotheses for future research (Whitehouse et al., 2012). These included better predictions of the effects of ritual frequency and systemic rigidity; the hidden complexities of frequency and intuitiveness; discoveries on the relationships between frequency, arousal, and motivation; a more nuanced insight into imagistic splintering and insights into the between-group competition among doctrinal traditions (Whitehouse et al., 2012, p. 197–198).

Perhaps one of the most significant advances in testing evolutionary theories of religion (or any theories of religion for that matter) is efforts in building databases that are longitudinal and fine-grained. Three separate yet linked databases are being developed by teams under the leadership of scholar of religion Edward Slingerland, Harvey Whitehouse, and Peter Turchin. In a signal article from 2012, they have sketched out the usefulness and design of such a database (Turchin et al., 2012). The goal of such databases is to test rival theories with historical data. This involves the following procedure:

- Specify the main question and identify empirical patterns that need to be explained.
- Develop a set of competing hypotheses that make different empirical predictions. This phase may require building mathematical models as an intermediate step, for example, when theories postulate a complex set of interrelated processes.
- Code the data and perform statistical analyses of the resulting database to determine which hypotheses most parsimoniously explain the empirical patterns. (Turchin et al., 2012, p. 273)

Turchin and colleagues have recently demonstrated the usefulness of this approach in testing his theory on the relations between war and the development of complex societies (Turchin et al., 2013).

Conclusion

Thus, there is an endless variety of evolutionary theories of religion, none of which have attained the status of fact. Many of the theories are plausible; however, very few are amenable to experimental design. Furthermore, the burgeoning field of the cognitive science of religion is still in the process of struggling with the same problems found in other psychological sciences, such as design, priming, replication, and cross-cultural validity. In the long run, the future is promising. With the development of longitudinal and fine-grained databases, it may become possible for scholars to test competing theories and reach more definitive conclusions, at the very least on which ideas should be rejected.

Religious Fundamentalism: Cultural Concerns

Martin E Marty, University of Chicago, Chicago IL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Religious fundamentalisms, reactions to the real or perceived threats to religion, have appeared in many nations, societies, and religions. Not merely individual responses to change, fundamentalisms appear in cultural forms, which means that they cohere as assemblages of beliefs and behavior patterns that become instruments for dealing with change and assaults. The content of each fundamentalistic response will be distinctive since it takes its character from existing but differing religions, but forms and practices appear to have some common characteristics across the boundaries of the religions.

'Fundamentalism' is the name applied to characterize a variety of modern religious movements internationally, but its use is contested in some cases. The key feature in these movements is their reactive character. That is, they are not simply traditional, classic, conservative, or orthodox. Scholars and others usually speak of fundamentalism only in cases that find sets of religious people responding to certain kinds of challenges. The challenges may vary, but they tend to be variations on what the reactors or observers ordinarily would call 'the modern,' 'modernity,' 'modernization,' or 'modernism.'

Fundamentalist Cultures

Fundamentalism, however defined, can be viewed and appraised as a deeply personal combination of beliefs and behaviors. Fundamentalism is ordinarily perceived as a social and cultural phenomenon, a religious presence or movement within particular denominations or religious traditions that attracts and inspires collectives of like-minded people who make up cultures or, more often, subcultures. To speak in these terms invites and demands some attention to what is meant by 'cultures'.

Philip Bagby, who gave much attention to comparative cultures, defined a culture as manifesting "regularities in the behaviour, internal and external, of the members of a society, excluding those regularities which are clearly hereditary in origin." (Philip Bagby, 1958. Culture and History: Prolegomena to the Comparative Study of Civilizations. University of California Press, Berkeley, p. 93.) Therefore 'culture' refers to elements in our experience. Thus one observes regularities among motorcyclists, who form a 'cyclist culture,' among addicted people in a 'drug culture,' among devotees of classical music who participate in a 'high culture' or who have their counterparts in 'mass culture.' Bagby goes on to define a culture also as a "distinctive assemblage of culture-traits and complexes regularly found together" (p. 93). Such distinctive assemblages can be visible, especially in the form of what people wear. Members of Amish culture clothe themselves quite differently than do the members of a 'country-club culture'. The culture traits and complexes found together will almost always be noted in distinctive languages – colloquial or academic and the likes – that separate the participants in a culture from others.

Observing such distinctive sets of traits and complexes is especially important in a phenomenon like fundamentalism. This is so because the boundaries between fundamentalist subcultures and people around them are on one hand very defined. Those who belong to them can discern almost instantly who 'belongs' and who is a stranger. Sometimes a label or a phrase, such as 'born again' among some sets of American Protestant fundamentalists, will serve as a signal. Orthodox Jewish cultures are very distinctive and easily discerned, while liberal or 'reform' Jewish cultures are less defined but their signals and traits are very important to participants as they define themselves.

The Term 'Fundamentalism'

One of the most controversial features of fundamentalist movements is the term itself. People in statecraft and scholars have reservations about the use of the term 'fundamentalist.' First, some question the accuracy and fairness of designating worldwide movements in many religions by using the name derived from one reactive movement in American Protestantism in the early twentieth century. Second, in the eyes of many, the transfer of this term to other religious contexts looks like an example of a western linguistic imperialism that needs to be resisted. Still others rightfully contend that features peculiar to a specific Protestant confiict differ in so many respects from those in other reactive movements that only confusion could result from the use of the term.

Another major reason why so many members of these cultures are reluctant to accept the term as their self-description or for scholarly purposes has to do with the fact that it can be used pejoratively and stigmatically. In a way, this resistance is ironic, since in the American context and, by analogy, in other religions and cultures, those who formed and originally adhered to such separatist and often militant movements originally *wanted* to be stigmatized, and still may want distinction, but on their own terms.

The American Protestant fundamentalists in the 1920s did not want to be confused with conservatives, regularly complaining that while the majority of their fellow-believers claimed to be conservative, they did not do battle for the divine cause. Because other Christians were too gentle and compromising, it was argued, a new term had to be coined and applied. This term would help provide boundaries around the movement and create distance between it and conventional conservatisms – or against anything else that implied a potential for compromise

 http://dx.doi.org/10.1016/B978-0-08-097086-8.84051-9

and comfortable adaptations to other cultures. But because the strategy of setting boundaries and deliberately seeking to offend others was often carried to extremes, many became discontented with the fundamentalists' self-chosen name. Some sought moderating terms, and in the American case, 'neo evangelicalism' and then 'evangelicalism' served this purpose.

The term 'fundamentalism' will not be found in dictionaries or encyclopedias, even encyclopedias of religion in America, before the time of a fundamentalist– modernist controversy in the United States, one that came to a climax around 1925. When the word did make its way into reference books after that period, for example in German or French dictionaries, all the meanings of fundamentalism were reduced to something about a battle over the verbal inerrancy and literal interpretation of the Christian Bible – a reduction at odds with some identifiers and confusing to observers of Islamic, Jewish, or other religions.

Given these burdens associated with the term, there is good reason to ask about its continued usefulness and appropriateness. Several reasons are cited in defense, among them the following: first, the word has made its way into common speech. So widespread is the use among reporters, scholars, and politicians that it is not likely to disappear because of discontent over its use by many. Better to clarify what is meant, it is said, than to invent new coordinating terms that will meet similar resistance in due course. The second reason has to do with the need for some such coordinating designations. To mention that need is, of course, to open the door to the many controversies over comparative methods. James (1902) typically made a defense of the practice of typifying and classifying. Without classifying, it is hard to understand many features of the phenomena. At the same time, James warned against the danger of losing the individual and particular character of the objects studied.

In the case of fundamentalism, the interest in coordination is almost entirely formal, not substantive. That is, one notices aspects of certain religious movements by studying characteristic features while being well aware that these movements all differ from each other in respect to content. Indeed, a Muslim fundamentalist will be 'doctrinally' more distant from a Protestant fundamentalist than modernists in both religions would be to each other. So there is no point in using the word 'fundamentalist' to characterize the central teachings of these religious expressions.

Even here, however, the line is a bit fuzzy. While fundamentalists reject modernity, paradoxically many are adept at using modern media such as radio, television, film, and the Internet to hold their groups together, seek converts, and express themselves to outsiders. That observation grows out of formal comparison. But a second generalization – that all the fundamentalisms are not only patriarchal but that in their talk about God, they stress God's maleness while moderate and modernist movements play down masculine references to deity – does show that there can be certain kinds of substantive similarities.

A third reason for using the term, say its defenders, is that no clear alternative is apparent. Some reporters, trying to avoid the word, will use something like 'militants,' appropriate for one dimension of some of their lives. But these words do not signal anything of cultural context: one can be militant about revenge, the search for territory, or any number of themes that have nothing to do with religious reaction. Further defense of the term comes from those who say that all words travel, and globally people would make little sense of each other if they did not have terms that could be reappropriated in a variety of cultures. Thus words like 'nationalism,' 'liberalism,' 'colonialism,' 'conservatism,' 'radicalism,' 'democracy,' and 'republicanism' were born within western contexts and get translated for usage elsewhere. The People's Republic of China means something very different with the term 'republic' than do those who speak of the United States as a republic. Yet there are reasons for people to use the term in both contexts – and then to clarify what they mean and point to differences.

Attempts to replace the term usually are specific and cannot be used for coordinative or comparative purposes. Thus, one might speak of 'radical revolutionary nationalist Islamic reform,' using other borrowed terms, and then find that they do not relate to phenomena in the Catholic or Hindu world, so it could not serve as a coordinating term. Mention of such instances suggests why many choose to use 'fundamentalism': it has acquired some rather specific meanings, meanings that deserve examination.

The Originating Instance in America as a Case Study

American Protestantism, having been divided into many denominations from the beginning, experienced some trans-denominational conflicts in the nineteenth century. The first great breach occurred between the North and the South in the Civil War, when churches on each side inspired, monitored, provided morale for, and negatively defined the other side in religious terms. But all through the century another split was taking shape, thanks to latent tensions between theologically more liberal and more conservative parties.

These tensions increased with the arrival in the United States after the middle of the nineteenth century of Darwinian evolution, the higher criticism of the Bible, and various forms of political progressivism. Many conservatives vehemently resisted theories of evolution, in part because these were seen as assaults on the Bible. They all rejected biblical criticism as a threat to the foundations of the faith. And progressivism did not do justice to apocalyptic messages in the Bible. Meanwhile, modernist parties began to develop toward the turn of the twentieth century. These were strongest at the prestigious theological schools such as Harvard, Yale, and Chicago – but rather dramatically not at Princeton University and Princeton Theological Seminary, from which some intellectual impetus for fundamentalism was to come.

Between 1910 and 1915, the conservative parties issued an influential set of booklets called *The Fundamentals*. From then on, the accent on 'fundamentals' grew. In 1919, a World's Christian Fundamentals Association was born. In 1920, during a battle for power in the Northern Baptist Convention, a Baptist editor proudly chose and publicized the term 'fundamentalist' for his faction. The Presbyterians, and to a lesser extent other mainstream Protestant denominations, entered into the battle. The celebrated Scopes trial in Tennessee in 1925, one that featured conflict over the teaching of evolution in public schools, was the best-known event in the formation and publicizing of fundamentalism.

This is not the place to trace in detail the outcomes of the struggles. Fundamentalists lost the battles for control, but

inventively went their way, developing their own Bible colleges, seminaries, mission boards, and, thanks to schisms, denominations. They were a presence but not a vivid one during this period. In 1941, some among them formed an American Council of Christian Churches, which engaged in rivalry with the more moderate National Association of Evangelicals born in 1942. Still regarded by nonfundamentalists as marginal, eccentric, and withdrawn, fundamentalists remained generally aloof from politics. However, during the 1970s most of them reversed their stance and began to adopt political interventionist postures. They have been a prominent presence ever since.

To detail this case study further might well bias the case of those who charge that global and interreligious use of the term 'fundamentalism' is too reliant on the American experience. But one could study cognate movements elsewhere – such as the Muslim Brotherhood in Egypt – and find similar reasons for Islamic conservative groups there to move into reaction. A description of elements that make up what is called 'fundamentalism' in any religion will be more profitable, however, than would extending the number of case studies.

A Phenomenological Approach to Fundamentalist Features

By 'phenomenological' here is meant a pattern of observation of cultures in which the analysts 'bracket' their presuppositions – in this case, for example, their assumptions about the positive or negative aspects of fundamentalism – and to ask: 'What stands out in the phenomena that have been called fundamentalist?' Another way to put it is: what phenomena developed in the twentieth century that occasioned the need for fresh naming – since words like 'conservative' and 'traditional' had been easily available? These questions enable one to escape the charge that a priori definitions color the observations. These are some of those features. First, while fundamentalisms originally were dismissed by others as 'the old-time religion' and while some parade themselves as traditional, they differ in significant respects from conservatisms. In the eyes of doctrinal, political, and sometimes even armed militant partisans, conservatives may be too passive. They are too content to let people in the world go about their business, without reckoning with them. If in any particular instance the cause being challenged is seen as divine – and we are here dealing only with religious fundamentalisms – for anyone to be content with tradition is a betrayal.

Fundamentalisms rise when historically conservative religious movements experience something that challenges them to their core. In Iran and elsewhere in the Middle East after the late 1970s, the challenger might be 'the Great Satan' of western imperialism, specifically, in the eyes of its enemy, in its American form. In hyper-Orthodox Israel, the threat to Jewish identity itself appears to parties such as Gush Emunim to derive from nonobservant, compromising Jews who might even let some of the land of Israel slip away in diplomatic negotiations. In the United States, the challenge in the 1920s came in more doctrinal ways, through contests over biblical literalism. But in all these cases, the threat had to be seen as total; fundamentalists do not bother much about trivial issues.

Because the challenges are encompassing, the response of fundamentalist movements has to be drastic. Fundamentalisms characteristically are reactive. They rise among communities that have been acted upon, and they act back. Very often they use the very instruments that had presented the challenge. If a nation–state is the ominous force, fundamentalists make efforts to win power, through the ballot if possible and through weaponry if necessary. Let it be noted that not all fundamentalisms take on any form of military or terrorist guise. Some even shun the political arena if they feel that they can convert sufficient recruits from that worldly zone or win their way simply through cultural militancy, as with disputes over 'values' and media. Again, fundamentalists tend to use some of the weapons that have brought change whenever, for example, they take instruments of mass media, the agents that penetrated their homes and consciousness, and become sophisticated in using these to fight back.

Somehow, in every case, they react. Not to be reactive in these contexts is to be not fundamentalist. George Marsden, the foremost historian of the American version of fundamentalism, describes a fundamentalist as 'an evangelical who got mad.' In reaction, the fundamentalist seeks ammunition for defense and aggression. Here is where the fundamentals come in. Fundamentalists reach back to foundations, some in the Qur'an, some in the Torah, some in the New Testament, still others in classic events of the past, and claim them for their own. In every case in their eyes there had to be some sort of golden moment or precious book to which arguing parties can resort to in efforts to determine winners and losers.

Acting upon these fundamentals, members of the group then engage, as noted, in setting boundaries. They are often described as bearing a Manichaean cast. This means that the cosmos is divided into God versus anti-God, good versus evil, our people versus everyone else. They may not necessarily withdraw into enclaves, but they will tend to use code words, slogans, and informal testing devices that help them screen out the most dangerous persons and forces, namely the moderates. The total outsider, the infidel, the Great Satan, is useful for mobilizing forces, but is not a threat in the way a compromising modernizer is seen to be.

With the setting of boundaries comes the claim that participants are an elect people, God's own instrument. They know something of where history is going; it has been revealed to them by sacred books in which they find the fundamentals. The elect people, called to represent God, must keep themselves pure, try to recruit others, and, to use the words from the American struggle in the 1920s, 'do battle for the Lord.' It is easier to be fundamentalist in 'religions of the book' such as Judaism, Christianity, and Islam, than it is in faiths such as Hinduism and Buddhism, where no single divine scriptural revelation is foundational. The battles may vary in character. Thus in most cases in the Islamic world the enemy is not external, but instead a regime seen as corrupt, secularizing, and compromising even though all its leaders are themselves practicing Muslims. In Israel, the parties called fundamentalist may engage in warfare against Arab Muslims, but they take the most pains in differentiating themselves from compromising Jews. Action may be hortatory, prophetic, political, military, or terrorist, though it is often only the latter two that draw the world's attention.

Accounting for Fundamentalisms in Culture

No scholar would claim that modern fundamentalisms have no counterparts or analogs in the past within the various religions. All of them have at times manifested forces of traditionalist reaction and conservative aggression. It is valuable to study these analogs. But the word 'fundamentalism' has more appropriately been reserved for responses to what has been seen as modern. One way to put it: these are reactive movements that appeared after the modern academy thought there would be no more like it, that the religions that survived would be small, weak, and always compromising.

In recent years, one of the most focused endeavors to understand fundamentalisms has been in the hands of psychologists, especially social psychologists. They have on occasion assessed persons in the movements or the movements as cultures, and generalized about their mentality. Participants, they note, tend to be people who cannot tolerate ambiguity, paradox, contradiction, or doctrinal and moral 'fuzziness.' There is evidence for this. Yet many scholars caution against what can be superficial assessments. It is, they observe, difficult to reduce fundamentalisms to this psychological cast, given the fact that people with such predilections in one culture turn religious fundamentalist and those in others do not. So to note the psychology of fundamentalists is a valuable bur insufficient measure unless it is directed to the peculiarities of cultures and their historic experiences. To define fundamentalisms as intense literalist devotion to sacred texts such as the Qur'an, the Torah, or the Christian Bible will be of little help in understanding fundamentalist-like movements, movements bearing family resemblances to fundamentalism in, say Buddhist societies and cultures whose religions are less determined by texts than are those characterized as 'people of the book,' such as Judaism, Islam, and Christianity.

The most helpful aspect of psychological studies of fundamentalist cultures is to try to determine what moves people to leave behind other religious preferences and to 'turn fundamentalist.' Numbers of studies focused on how religious texts are put to work or, to turn this around, how psychological interests turn people to texts to reinforce their searches and to help discredit others. Political and social scientists perceiving fundamentalisms in culture often relate the rise of such movements to class conflict. Marxist interpretations, for example, can see fundamentalisms as futile resistances by people who take resort in otherworldly solace when they can do little to gain in this world. It is true that in many instances it is the poor and apparently powerless who do turn to fundamentalism. But it is also true that those who react may do so from the comfortable confines of a Princeton Theological Seminary and Princeton University in the 1920s, as did the intellectual definers of early American fundamentalism. And one will find fundamentalists of wealth in many of the American cities and note that some among them extravagantly fund fundamentalist projects. Class analysis does contribute to understanding the phenomena, but most scholars again resist reductionism of a sort that fundamentalists are 'nothing but' this or that. Instead, they give evidence that fundamentalists experience complex responses and reactions to many kinds of cultural stimuli, and as such manifest features that are best appraised with a variety of perspectives and disciplines. Among these would be humanistic efforts to bring to bear history, philosophy, and religious studies.

One way to approach the study is to listen as anthropologists do for 'agent's description.' Someone who pays attention to, records, and coordinates the testimony of fundamentalists in many religious contexts will find that the issues that evoke response begin very close to the self of the believer. Diplomats, reporters, and scholars often begin at the furthest extensions of fundamentalisms, as when some engage in terrorism or revolutionary military action.

Fundamentalist believers begin by defending a worldview, including one that has been recently changed, thanks to conversion. The world looks different to someone who is an initiate, 'born again' in some versions, than it does to someone else who is distant from or quiet about religious impulses. Very close to that egocenter is the question of personal, social, and cultural identity. To whom do I belong? Whom can I trust? With whom can I check signals and from whom do I draw inspiration? Those who ask such questions in the erosive climate and culture of late modernity find that identity becomes a major question. They also note that it is threatened by forces such as travel, modern mass communications, and mass higher education, especially where the challenges of pluralism and relativism are fierce.

As close to the center of the person as are worldview and identity is the issue of gender. Fundamentalists preoccupy themselves with what it means to be a man or a woman. The Manichaean differentiation is strong: there is no room for ambiguity in defining gender. The fundamentalisms, for example, all reject homosexual expression. From gender they move to defense of family. In all the cultures studied by fundamentalist scholars, 'family values' and shoring up the family, however defined, are central to the program.

From the orbits of gender and family one moves to other challenges. Thus, one's mind and habits are shaped by mass communications, and fundamentalists tend to react by trying to screen out uncongenial images, to engage in boycotts, or attempt legally to censor and exclude broadcast or published materials that they believe to be evil or subversive of their values.

Education is another zone in which fundamentalists do battle. They start their own schools to protect and nurture their own young and often engage in efforts to subvert the character of others' schools, especially the public's schools, when their teaching and habits are offensive. Similarly, many of them have challenged modern medical practices, and make the clinic their arena of conflict. They organize against abortion, euthanasia, and many forms of treatment that violate their view of the body as God's temple.

In the sphere of economics it is harder to generalize. Some religious texts favored by fundamentalists – notably those detailing *shari'ah*, or Islamic law – may be explicit as when they proscribe the taking of interest. But some fundamentalist movements promote communal, one might say communistic, economic patterns, while others, notably in North America, often align themselves with *laissez-faire* economic forces. But when they perceive economic circumstances as a threat to them, they may adopt any number of strategies, and find their holy books less defining and definitive in setting boundaries and distancing others.

When it comes to efforts to change politics, for example, it is through the use of the instruments of political propaganda,

the ballot, and constitutional revision that fundamentalists find themselves reckoned with most strenuously. Where they cannot take over a regime, they may in God's name undertake revolutionary activity. It is activity of that sort that elicits headlines about fundamentalist militants around the world.

Curiosity about the work of historians and social or cultural analysts of fundamentalisms might have been confined to theology schools, strategists in the institutional life of religious organizations, or curators of religious museums or libraries. However, a turn that modern fundamentalisms took in the last decades of the twentieth century changed all that. Frustrated or ambitious fundamentalists who claimed that they knew that God was on their side, lost patience waiting for victory and took history into their own hands. Although Hindu fundamentalists came to power in a variety of parties and movements around 1925 in India and Muslims in Egypt formed a Brotherhood in 1928, there as elsewhere the political stirrings did not evolve into military action, until the Post-Cold War era, in a world often described as 'secular,' when some fundamentalists turned militant, as in the Iranian Revolution in 1979–80. Similarly extreme fundamentalist movements developed in Saudi Arabia and elsewhere in the Middle East. Most notable was the formation of al-Qaeda, which became the best-known terrorist organization, and which waged subversive activities and war in the name of Allah. What began as a search for meaning became an assertion of power.

Although many fundamentalist movements began among people who wanted to be distanced from others, including from the religious movements from which they sprang or with which they might be confused, in a drastic turn observable globally, numbers of these changed completely. Where fundamentalists had once been otherworldly, now they wanted to take over portions of the world. Fundamentalists had separated from the state, but in a later version they wanted to take over the state. Whereas they had once tried to hide from 'the world,' now they aspired to transform the world in images the fundamentalists chose. Observers and leaders of state and the economy frequently ask if the fundamentalists will win. That is impossible to answer, but the fact that some aggressive fundamentalist movements have experienced setbacks in cultural battles indicates that they are not all-powerful. Many other factions among them, in the course of time, grew weary or chose to compromise and adapt to elements in the surrounding cultures. In every case, however, their very presence would have been a surprise to people who, a century before they appeared, had not envisioned that in a world of technology and devotion to reason, such intense and dedicated religions might arise, to put on the defensive many secular and moderate movements. The key test in all cases in the future will be: does the movement possess sustaining religious energies, or is it almost entirely a reaction to modernity with its many faces and challenges?

Abstract

In the global era of the post–Cold War world, secular nationalism is in peril. As demographic shifts, transnational economic networks, and transnational forms of communication have undermined traditional notions of nationalism, local leaders have searched for new anchors to ground their social identities and political loyalties. Many have turned to ethnicity and religion. Although many of the framers of the new nationalisms have reached back in history for ancient images and concepts that will give them credibility, theirs are not efforts simply to resuscitate old ideas, these are contemporary ideologies that meet present-day social and political needs. In the modern context the notion that indigenous culture can provide the basis for new political institutions, including resuscitated forms of the nation-state, is revolutionary. And for this reason, the encounters between religious nationalism and the secular state are sometimes violent.

The late twentieth century and the first decade of the twenty-first was a remarkable era of strident religious protest around the world. Beginning with the Ayatollah Khomeini's Islamic revolution in Iran in 1979 and the Khalistani movement of Sikhs in northern India in the 1980s, movements of religious politics asserted themselves in all major religious traditions: Jewish militants in Israel, Hindu nationalists in India, Christian militia in the United States, Buddhist extremists in Sri Lanka, and Muslim activists in the Middle East. In some cases, such as the jihadi terrorists associated with al-Qaida, the goal was transnational. In most other instances of religious politics, including the Iranian and Sikh cases, the goal was a new form of religious nationalism. Both rejected the secular nationalism that had been the central feature of European Enlightenment since the eighteenth century.

The new religious movements were largely reactions to the worldwide spread of secular modernity. They were responses to the insufficiencies of what is often touted as the world's global political standard: the secular, Westernized constructs of nationalism that are found not only in the West but also in many parts of the former Third World as vestiges of European colonialism. These secular nationalisms, weakened by globalization, have been under siege. Their vulnerability has enabled new ethnic and religious politics to step into the breach and shore up national identities in their own distinctive ways. Yet these identities have often had international and transnational aspects of their own. Thus some forms of ethnic and religious politics have been global, some virulently antiglobal, and still others stridently nationalistic. Yet all have preyed upon the weakened state of secular nationalism in the present period of late modernity.

Religious Challenges to the Secular State

The idea of the modern nation-state, the political legacy of the European Enlightenment, is at once profound and simple: the state is created by the people within a given national territory. Secular nationalism – the ideology that originally gave the nation-state its legitimacy – contends that the authority of a nation is based on the secular idea of a social compact of equals rather than on ethnic ties or sacred mandates. It is a compelling idea, one with claims to apply universally. It reached its widest extent of worldwide acceptance in the first half of the twentieth century with the creation of scores of new independent nations at the end of the era of European colonialism.

But the second half of the century turned out to be a different story. The secular nation-state proved to be a fragile artifice, especially in those many areas of the world where nations had been created by retreating colonial powers – in Africa by Britain, Portugal, Belgium, and France; in Latin America by Spain and Portugal; in South and Southeast Asia by Britain, France, the Netherlands, and the United States; and in Eurasia by the Soviet Union. In some cases boundary disputes led to conflicts between neighboring nations. In others the very idea of the nation caused suspicion.

Many of these 'imagined nations,' as Benedict Anderson (1983) has called them – some with invented names such as Pakistan, Indonesia, and Yugoslavia – were not accepted by all within their territory. In other cases the tasks of administration became difficult to perform. In many cases the newly created nations had only brief histories of prior colonial control to unite them, and after independence they had only the most modest of economic, administrative, and cultural infrastructures to hold the disparate regions within them together.

By the 1990s these ties had begun to fray. The global economic market undercut national economies, and the awesome military technology of the United States and NATO reduced national armies to border patrols. More significant, the rationale for the nation-state came into question. With the collapse of the Soviet Union and the postcolonial, post–Vietnam critique of Western democracy, the secular basis for the nation-state seemed increasingly open to criticism. In cases such as Yugoslavia, when the ideological glue of secular nationalism began to dissolve, the state fell apart.

The effect of what I have elsewhere called 'the loss of faith in secular nationalism' was devastating (Juergensmeyer, 2008). It seemed that nationalism was being challenged everywhere, and the scholarly community joined in the task of trying to

understand the concept in a post–Cold War and transnational era (Kotkin, 1994; Smith, 1995). Part of the reason for the shaky status of nationalism was that it was transported to parts of the world in the cultural baggage of what Jürgen Habermas (1997) has called 'the unfinished project of modernity' – a trust in reason that was by now considered obsolete. In a multicultural world, where a variety of views of modernity are in competition, the very concept of a universal model of secular nationalism became highly debatable.

Globalization has challenged the modern idea of nationalism in a variety of ways. These challenges have been varied because globalization is multifaceted. The very term 'globalization' refers not to any one thing but to a series of processes. It embraces not only the global reach of transnational businesses but also their labor supply, currency, and financial instruments. In a broader sense globalization also refers to the planetary expansion of media and communications technology, popular culture, and environmental concerns. Ultimately, it also includes a sense of global citizenship and a commitment to world order.

Globalization has affected societies in differing ways. Some countries that have been brought into contact with economic globalization – by supplying labor for the commodity chains of globalized production – have not experienced the globalization of culture and citizenship. The advent of economic globalization has threatened local identities in such a way as to encourage the protection of local cultures and social identities, sometimes in hostile and defensive ways. This effect has been observed by Benjamin Barber, who notes that the 'McWorld' of contemporary Westernized culture has assaulted the public consciousness in various parts of the world. In extreme forms the reaction has been the 'jihad' of militant tribalism (1995).

Some of the most intense movements of ethnic and religious nationalism have arisen in nations which have felt themselves exploited by the global economy, such as in Iran and Egypt, or else have believed that somehow the benefits of economic globalization are passing them by (Juergensmeyer, 2003, 2008). The global shifts in economic and political power that occurred following the breakup of the Soviet Union and the sudden rise and subsequent fall of Japanese and other Asian economies in the last decade of the twentieth century have also had significant social repercussions. The public sense of insecurity that came in the wake of these changes was felt especially in areas economically devastated by the changes, including those nations that had been under the dominance of the Soviet Union.

These shifts led to a crisis of national purpose in less developed nations as well. Leaders such as India's Jawaharlal Nehru, Egypt's Gamal Abdel Nasser, and Iran's Riza Shah Pahlavi had tried to create their own versions of America – or else a cross between America and the Soviet Union. But a new, postcolonial generation no longer believed in the Westernized vision of Nehru, Nasser, or the Shah. Rather, it wanted to complete the process of decolonialization by asserting the legitimacy of their countries' own traditional values in the public sphere and by constructing a national identity based on indigenous culture. This eagerness became all the more keen with the global media assault of Western music, videos, and films – an assault that has threatened to obliterate local and traditional forms of cultural expression.

In other cases it was a different kind of globalization – the emergence of multicultural societies through global migrations and the suggestion of global military and political control in a 'new world order' – that caused fear. Perhaps surprisingly, this response was most intense in the high-income countries, which in other ways seemed to be the paradigm of globalization. In the United States, for example, the Christian Identity movement and militia organizations were fueled by fears of a massive global conspiracy of liberal American politicians and the United Nations. In Japan a similar conspiracy theory motivated leaders of the Aum Shinrikyo movement to predict a catastrophic World War III, which their nerve gas assault in the Tokyo subways was meant to emulate.

As farfetched as the idea of a 'new world order' of global control may be, there is some truth to the notion that the globalization of culture has brought the world closer together. Although it is unlikely that a cartel of malicious schemers plotted this global trend, its effect on local societies and national identities has nonetheless been profound. Globalization has undermined the modern idea of the nation-state by providing nonnational and transnational forms of economic, social, and cultural interaction. The global economic and social ties of the inhabitants of contemporary global cities are linked together in a way that supersedes the Enlightenment notion that peoples in particular regions are naturally linked together by a social contract. In a global world it is hard to say where one region ends and another begins. In fact, it is hard to say how the 'people' of a particular nation should even be defined.

Religion and ethnicity have stepped in to redefine public communities. The fading of the nation-state and of old forms of secular nationalism has produced both the opportunity and the need for new nationalisms. The opportunity has arisen because the old orders have become so weak. The need for national identity persists because no single alternative form of social cohesion and affiliation has yet appeared to dominate public life, the way the secular nation-state did in the twentieth century. In a curious way traditional forms of social identity have helped to rescue the idea of national societies. In the continuing absence of any other demarcation of national loyalty and commitment, these old staples – religion, ethnicity, and traditional culture – have become resources for national identification.

Nationalism Defined by Religion

Today religious rather than secular nationalism has provided a solution to the problem of Western-style secular politics in a non-Western and multicultural world. As secular ties have begun to unravel in the post–Soviet and postcolonial era, local leaders have searched for new anchors to ground their social identities and political loyalties. Many have turned to ethnicity and religion. What is ideologically significant about these ethnic and religious movements is their creativity. Although many of the framers of the new nationalisms have reached back in history for ancient images and concepts that will give them credibility, theirs are not efforts simply to resuscitate old ideas. These are contemporary ideologies that meet present-day social and political needs.

In the modern context the notion that indigenous culture can provide the basis for new political institutions, including resuscitated forms of the nation-state, is revolutionary. Movements that have supported ethnic and religious nationalism have therefore often been confrontational and violent. They have rejected the intervention of outsiders and at the risk of being intolerant have pandered to indigenous cultural bases and have enforced traditional social boundaries. It is no surprise, then, that they have gotten into trouble with one another and with defenders of the secular state. Yet even these conflicts with secular modernity have served a purpose for the movements. They have helped define who they were as people and who they were not – for example, not secularists.

Since secularism has often been targeted as the enemy, that enemy has most easily been symbolized by things American. The United States has taken the brunt of religious and ethnic terrorist attacks in recent years, in part because it so aptly symbolizes the transnational secularism that the religious and ethnic nationalists loathe and in part because the United States does indeed promote transnational and secular values. For instance, the United States has a vested economic and political interest in shoring up the stability of certain regimes around the world. This interest often puts the United States in the position of defending secular governments. Moreover, the United States supports a globalized economy and a modern culture. In a world where villagers in remote corners of the world increasingly have access to MTV, Hollywood movies, and the Internet, the images and values that have been projected globally have been American.

It is thus understandable that since the United States is seen by many in traditionally religious countries as promoting a global secular agenda it is often disdained by. The demonization of the United States by many ethnic and religious groups fits into a process of delegitimizing secular authority. In order to delegitimize the public authority, the religious groups have had to shore up their own pillars of authority. In doing so, they have appropriated traditional religious images, especially that of cosmic war. In this scenario, competing religious groups are seen as foes and scapegoats, and the secular state is viewed as the enemy of religion. This 'satanization' is aimed at reducing the power of opponents by discrediting them. By humiliating them – by making them subhuman – religious groups assert the superiority of their own moral power.

During the early days of the Persian Gulf War in 1991, the Hamas movement issued a communique stating that the United States 'commands all the forces hostile to Islam and the Muslims' and singled out then-President George Bush as not only 'the leader of the forces of evil' but also 'the chief of the false gods.' As late as 1997, Iranian politicians, without a trace of exaggeration, described America as the 'Great Satan.' This rhetoric first surfaced in Iran during the early stages of the Islamic revolution, when both the Shah and President Jimmy Carter were referred to as Yazid ('agent of Satan'). 'All the problems of Iran,' the Ayatollah Khomeini elaborated, are "the work of America" (Khomeyni, 1977: p. 3). He meant not only political and economic problems but also cultural and intellectual ones, fostered by "the preachers they planted in the religious teaching institutions, the agents they employed in the universities, government educational institutions, and publishing houses, and the Orientalists who work in the service of the imperialist states" (Khomeini, 1985: p. 28).

Religious Nationalism in the Global Era

When members of the extreme religious right in the United States recoil in horror over what they call 'the New World Order,' what they and members of many other radical religious groups around the world fear is not just globalization, but also the secular aspects of globalization. They are afraid that global economic forces and cultural values will undercut the legitimacy of their own bases of identity and power. By contrast, other aspects of globalization – technical and economic – are often perceived as neutral and even useful. Osama bin Laden exploited to spread his messages, and members of the al-Qaida network have at times relied on encrypted Web sites for communication.

Some groups have a global agenda of their own, a transnational alternative to political nationalism. Increasingly, terrorist wars have been waged on an international and transnational scale. When the World Trade Center was demolished in the dramatic aerial assaults of 11 September 2001, it was not just the United States that was targeted but also the power of the global economic system that the buildings symbolized. Osama bin Laden's al-Qaida network was itself a global structure. The Gamaa i-Islamiya group, related to al-Qaida, literally moved its war against secular powers abroad when its leader, Sheik Omar Abdul Rahman, moved from Egypt to Sudan to Afghanistan to New Jersey. It was from the Jersey City location that his followers organized the 1993 bombing attack on the World Trade Center that killed six and injured a thousand. Osama bin Laden's operative, Ramzi Youssef, also convicted of complicity in the 1993 World Trade Center bombing, masterminded the 'Bojinka Plot' that would have destroyed a dozen US commercial planes over the Pacific during the mid-1990s. Youssef moved from place to place throughout the world, including Pakistan and the Philippines. Algerian Muslim activists brought their war against secular Algerian leaders to Paris, where they have been implicated in a series of subway bombings in 1995. Hassan Turabi in Sudan has been accused of orchestrating Islamic rebellions in a variety of countries, linking Islamic activists in common cause against what is seen as the great satanic power of the secular West. Osama bin Laden, from his encampment in Afghanistan, was alleged to have ordered many acts of terrorism around the world.

These worldwide attacks may be seen as skirmishes in a new Cold War or, more apocalyptically, a 'clash of civilizations,' as Samuel Huntington has termed it (see Huntington, 1996). It is possible to imagine this clash if one assumes that Islam and other religions are civilizations comparable with the modern West, or if one regards secular nationalism as, in the words of one of the leaders of the Iranian revolution, 'a kind of religion.' Those religious opponents of secular nationalism who regard it as religious often describe it as a religion that is peculiar to the West, a point echoed by leaders of the Muslim Brotherhood in Egypt.

Behind this image of a clash of cultures and civilizations is a vision of social reality, one that involves a series of concentric

circles. The smallest are families and clans; then come ethnic groups and nations; the largest and most important are religions. Religions here are not just bodies of doctrine and communities of believers but shared worldviews that span great expanses of time and space. They are global civilizations. Among these are Islam, Buddhism, and what some who hold this view call 'Christendom,' 'Western civilization,' or 'Westernism.' The so-called secular culture of places such as Germany, France, and the United States stand as subsets of Christendom/Western civilization. Similarly, Egypt, Iran, Pakistan, and other nations are subsets of Islamic civilization. From this vantage point it is both a theological and a political error to suggest that Egypt or Iran should be thrust into a Western frame of reference. By this view of the world they are intrinsically part of Islamic, not Western, civilization, and it is an act of imperialism to think of them otherwise. Proponents of Islamic nationalism often see themselves as a part of a larger, global encounter among Western, Islamic, and yet other cultures. This clash of civilizations view is not confined to the imaginations of either Samuel Huntington or a small number of Islamic extremists but has animated much of the political unrest at the dawn of the twenty-first century.

An even more extreme version of this global cultural clash has been an apocalyptic one, in which contemporary politics has been seen as fulfilling an extraordinary religious vision. Some Messianic Jews, for instance, think the Kingdom that will arise with the coming of the Messiah is close at hand. It will occur when the biblical lands of the West Bank are returned to complete Jewish control and when the Jerusalem Temple described in the Bible is restored on its original site, one presently occupied by the Muslim Dome of the Rock. Several Jewish activists have been implicated in plots to blow up the shrine in order to hasten the coming of the Kingdom. One who served time in prison for his part in such a plot said that the rebuilding of the Temple was not just a national obligation but an obligation for redemption of the world.

Religious activists such as Millennarian Christians and Shi'ite Muslims, who have a strong sense of the historical fulfillment of prophecy, also look to a religious apocalypse that will usher in a new age. American Christian political activists such as Pat Robertson and the late Jerry Falwell are animated by the idea that the political agenda of a righteous America will help to usher in an era of global redemption. The leader of Aum Shinrikyo, borrowing Christian ideas from the sixteenth-century French astrologer Nostradamus, proclaimed the coming of Armageddon in 1999. Those who survived this World War III – mostly members of his own movement – would create a new society in 2014, one led by Aum-trained 'saints.'

Activists in other religious traditions have seen a righteous society established in a less dramatic manner. Some Sunni Muslims, Hindus, and Buddhists have in their own ways articulated hopes for a political fulfillment of a religious society. They believe that "dhammic society can be established on earth," as one activist Buddhist monk in Sri Lanka puts it, by creating a religious state. These forms of religious politics are more than nationalist because they envision the world as caught up in a cosmic confrontation, albeit one that will ultimately lead to a peaceful world order constructed by religious nations. The result of this process will be a global order radically different from secular versions of globalization, but it will still be an ideological confrontation on a global scale.

The Future of Religious Nationalism

The goal of other religious activists is the revival of a nation-state that avoids the effects of globalization. Where new religious states have emerged, they have tended to be isolationist. In Iran, for instance, the ideology of Islamic nationalism that emerged during and after the 1979 revolution from the Ayatollah Khomeini and his political theoretician, Ali Shari'ati, was intensely parochial. It was not until some 20 years later that new movements of moderate Islamic politics encouraged its leaders to move out of their self-imposed international isolation. The religious politics of Afghanistan, especially after Taliban militants seized control in 1995, were even more strongly isolationist. Led by members of the Pathan ethnic community who were former students of Islamic schools, the religious revolutionaries of the Taliban established a self-contained autocratic state with strict adherence to traditional Islamic codes of behavior. Only after the collapse of the Taliban in 2001, following the al-Qaida terrorist attacks, did Afghanistan become more open to the wider world.

Other movements of religious nationalism have not been quite so isolationist. In India, when Hindu nationalists in the Bharatiya Janata Party (BJP), or 'Indian People's Party,' came to power in 1998 – a victory that was consolidated in the national elections of 1999 – some observers feared that India would become isolated from world opinion. The testing of nuclear weapons as one of the BJP's first acts in power did little to dispel these apprehensions. But in many other ways, including its openness to economic ties and international relations, the BJP has maintained India's active role in the world community. Credit for this openness may go in part to the moderate leadership of the former BJP Prime Minister, Atal Bihari Vajpayee, one of the country's most experienced and temperate politicians.

It is an open question whether movements of religious and ethnic nationalism elsewhere in the world, if they ever come into power, will behave like the Taliban or like the BJP. The movements in Pakistan, Egypt, and Algeria could go either way. When Abdurrahman Wahid, a Muslim cleric, edged past the daughter of Indonesia's founder to become the country's Prime Minister in 1999, observers wondered whether he would usher in an era of religious nationalism. In this case the fears were unfounded. The actions of his government showed Wahid's brand of Islam to be moderate and tolerant, one committed to bringing Indonesia into the world community and the global economic market.

In other regions of the world it has not been the creation of new religious states that has been at issue but instead the breakdown of old secular states with no clear political alternative. In some instances religious activists have contributed to these anarchic conditions. In the former Yugoslavia, for instance, the bloodshed in Bosnia and Kosovo was caused as much by the collapse of civil order as by the efforts to create new ethnic and religious regions. Because these situations have been threats to world order, they have prompted the

intervention of international forces such as NATO and the UN. It is, however, world order itself that many of these religious nationalists have opposed. They note that the increasingly multicultural societies of most urban communities around the world have undermined traditional cultures and their leaders. They have imagined the United States and the United Nations to be agents of an international conspiracy, one hell-bent on forming a homogenous world society and a global police state. It was this specter, graphically described in the novel *The Turner Diaries* by Andrew Macdonald, that one of the novel's greatest fans, Timothy McVeigh, had hoped to forestall by attacking a symbol of Federal control in America's heartland, the Oklahoma City Federal building, killing hundreds. In Norway, in July 2011, Anders Breivik undertook a massacre of young people in a summer camp sponsored by a liberal political party; in his manifesto, Breivik identified multiculturalism as the enemy. These, and other terrorist attacks around the world such as Osama bin Laden's bombing of US embassies in Africa in 1998 and of the *USS Cole* in Yemen in 2000, were acts of what might be considered to be a kind of 'guerrilla antiglobalism.'

Ultimately, however, it seems likely that despite these efforts to ignore or reject the forces of globalization, transnational cultures will expand, and that among them will be elements of religion and ethnicity. One future form of religious transnationality may emerge from the international relations of kindred religious states. According to one theory of global Islamic politics that circulated in Egypt in the 1980s and 1990s, local movements of Muslim politics were meant to be only the first step in creating a larger Islamic political entity – a consortium of contiguous Muslim nations. In this scenario, religious nationalism would be the precursor of religious transnationalism. Transnational Islam would lead to Islamic versions of such secular consortia as NAFTA and the European Community. In this Islamic model, however, the divisions among states would eventually wither away, and a greater Islamic union would arise.

A second kind of transnational association of religious and ethnic activists has developed in the diaspora of cultures around the world. Rapid Internet communication allows members of ethnic and religious communities to maintain a close association despite geographic dispersion. These 'e-mail ethnicities' are not limited by political boundaries or national authorities. Expatriate members of separatist communities such as India's Sikhs and both Sinhalese and Tamil Sri Lankans have provided funding for their compatriots' causes. In the case of Kurds their 'nation' is spread throughout Europe and the world, united through a variety of modern communications. In some cases these communities long for a nation-state of their own. In other cases they are prepared to maintain their nonstate national identities for the indefinite future.

Each of these futures harbors a paradoxical relationship between the national and the globalizing aspects of religious politics. This relationship suggests that there is a symbiotic relationship between certain forms of globalization and religious nationalism. It may appear ironic, but the globalism of culture and the emergence of transnational political and economic institutions enhance the need for local identities. They create the desire for a more localized form of authority and social accountability. In an era of globalization the crucial problems are identity and control. The two problems are linked, in that a loss of a sense of belonging leads to a feeling of powerlessness. At the same time what has been perceived as a loss of faith in secular nationalism is experienced as a loss of agency as well as of identity. For all these reasons the assertion of traditional forms of religious identities is tied to attempts to reclaim personal and cultural power. In this sense the various movements of religious nationalism that have arisen at the turn of the twenty-first century can be seen as attempts to regain social control.

Religious Organizations

Abstract

Religious organizations are diverse and distinctive while sharing characteristics with other types of organization. Pioneering studies identified types and subtypes, but more recent research has focused on the dynamics of religious organizations in respect of their forms of authority, governance, and leadership. There are wide variations in leadership roles, local settings, congregational forms, and patterns of recruitment and training. Religious organizations raise questions about the growing visibility of religious international nongovernmental organizations at the UN; the development of Buddhist, Hindu, Muslim, and Sikh organizations in liberal democracies; and the salience of legal questions arising from the growth of religious diversity.

Definitions of religion are varied and contentious. The notion of religious organizations is equally challenging because it seems to assume that the distinction between religion and nonreligion is analytically useful and can be drawn clearly. In fact, ambiguity and uncertainty cast doubt on the distinction, especially if the term 'spirituality' is also taken into account. A better approach than attempting a clear distinction is to regard the boundary between religious, spiritual, and nonreligious organizations as flexible, porous, and shifting. This approach places religious organizations on a sliding scale: at one end of the scale, they share much in common with other organizations or movements while, at the other, they retain characteristics which mark them out as significantly different. If the defining characteristic of religions is their assumption that deities, supernatural orders, or superhuman beings are active agents in the human world, then religious organizations are likely to be considered highly distinctive. If, on the other hand, religions are defined in terms of more inclusive assumptions about ultimate truth, the 'felt whole,' human flourishing, or the sacredness of the human world and its natural environment, then religious organizations are less likely to appear markedly different from other voluntary and communal organizations.

In short, attempts to draw a sharp distinction between religious and nonreligious organizations divert our attention from relevant overlaps between these two types of organizations (Demerath and Schmitt, 1998). Research on religious organizations therefore seeks to identify the extent to which they are significantly different from other organizations in terms of their personnel, goals and values, production processes, products, resources, authority structure, and networks. Examples include religious codes of law, charismatic religious leadership, and the potential of religious convictions for motivating donations of time and money to faith-based organizations. At the same time, the distinction between religious and nonreligious organizations may be important for legal or material reasons. For example, taxation advantages or exemption from antidiscrimination laws are available to organizations defined as religious in some countries. The consequences of failing to meet official criteria defining religious organizations can be grave in respect of groups claiming conscientious objection to compulsory military service or eligibility to provide chaplains in hospitals, prisons, or military establishments. Scholarly interest in questions about law and regulation of religious organizations increased strongly in the first decade of the twenty-first century, as did corresponding concerns with the freedom of religion.

Diversity and Distinctiveness

Religious organizations take many different forms, although the focus of their activities is typically on worship, prayer, meditation, teaching, healing, and spiritual well-being. These core activities are rooted in the revelations, texts, codes, laws, and principles which are regarded as authoritative by the people who identify or associate with particular religious organizations. Some of these people are, if we use the metaphor of markets, merely 'clients' who consult healers, spirit mediums, gurus, seers, or shamans. But others have strong and long-lasting commitments to transnational organizations such as the Roman Catholic Church, the Gülen movement, or Soka Gakkai International. Even the most formal, hierarchically structured religious organizations provide space for informal activities and relationships.

Religious organizations are also highly diverse in terms of their 'products,' and production processes. They typically produce sacred knowledge, sacramental acts, transcendental experiences, prophecies, worship and meditation, healing rituals, rites of passage, religious ethics, and social welfare programs. These products are delivered by professional and lay specialists, monks and nuns, recruiting missions, education programs, publishing and broadcasting activities, political and social movement campaigns, social service agencies, and local fellowships. The effectiveness of these activities depends largely on the capacity of religious organizations to secure adequate resources, to motivate, regulate, and train their personnel and followers, to coordinate their programs, to cope with dissent and indifference, to communicate with their environments, to defend their market share, and to deter free riders. It is typical of religious organizations to pursue their interests by establishing local fellowships, professional and lay ministries, regional, national, and international sources of authority, seminaries, schools, hospitals, welfare agencies, chaplaincies, publishing enterprises, and missionary orders.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.84044-1

In addition, many religious organizations participate in ecumenical or interfaith activities that cut across the boundaries of individual organizations, giving rise in some cases to higher-level organizations. In turn, interfaith bodies can function not only as sites of discussion but also as representative agencies that may be consulted by public authorities at local and national levels. Indeed, the public significance of interfaith organizations increases in countries where there is a growing diversity of religions. Nevertheless, the question remains open of whether official recognition of interfaith organizations undermines the authority of each separate religion and leads to a form of 'generic' religion. This problem is less likely to occur when religious organizations form alliances with one other for practical purposes such as challenging laws that are perceived to be damaging to shared interests, or joining *amicus curiae* submissions to courts of law in cases where the issues appear to affect religious organizations as a category.

History

The study of religious organizations has developed in two main streams. The first is concerned primarily with their distinctiveness and their subtypes. The second deals with their internal dynamics and their varying fortunes in different environments.

Types and Subtypes

Relations between religion and modernity were at the root of the pioneering studies that Max Weber (1864–1920) and Ernst Troeltsch (1865–1923) made of religious organizations. Weber highlighted the crucial contributions made by Ancient Judaism and Christianity toward the rationalization of the modern world and the differentiation of religion from other institutions. He argued that secularization, bureaucratization, and the disenchantment of the modern western world had all reduced the social significance of religious organizations. Although church-type organizations (large, territorially based, and inclusive in membership terms) still retained the potential to exercise power, Weber thought that their ties to the secular world hindered the translation of their Christian ethics into effective programs of action. By contrast, he believed that sect-type organizations (voluntaristic, relatively small, and exclusive in membership terms) which retained distinctive and radical versions of Christian theology and ethics were nevertheless unable to influence the world around them because they kept their distance from it. A major challenge for religious organizations is to achieve a suitable balance between the search for power and the retention of ideological purity.

The process of rationalization was of less interest to Troeltsch. His concern was with the historical evolution of the social forms of 'church,' 'sect,' and 'mysticism' to which the New Testament's ethics had given expression. The main question for Troeltsch was whether liberal Protestantism was sufficiently robust and well adapted to modernity to act as a social and political vehicle for Christian ethics in a secularizing world.

Subsequent generations of sociologists have used 'church,' 'sect,' and 'cult' – as well as variants such as 'established sect' and 'denomination' – to analyze patterns of continuity and change among religious organizations not only in Christianity but also in other faith traditions. Despite the difficulties of adapting these concepts to traditions such as Hinduism, Islam, and Buddhism, the concept of sect is still employed in analyses of religious movements in many parts of the world. Bryan Wilson's (1970) scheme of seven subtypes of sects remains especially influential. The concept of 'cult' has come to figure prominently in popular, as well as scholarly, discussions of religious movements such as the Unification Church, the Hare Krishna movement, and the Church of Scientology, all of which became controversial in the 1970s.

Beginning in the 1980s, the concepts of 'sect' and 'cult' underwent further development as proponents of rational choice – or religious economies – theory offered novel explanations of the capacity of 'high demand' religious organizations to attract and retain members. The theory held that certain people are rationally willing to incur the relatively heavy costs of participating in strict religious organizations such as sects and cults in order to obtain supernatural compensators which purport to give convincing answers to questions of ultimate meaning. It also depicted churches as offering answers that conformed to prevailing societal norms and values and were therefore unable to offer the selective benefits that sects and cults provided exclusively for their members in return for incurring high costs. Rational choice theorizing thereby tried to account for the historical formation of sects (by schism) and of cults (by innovation) as a never-ending process of competition in religious markets between religious organizations standing in different degrees of tension with culture and society (Iannaccone, 1988).

The basic concept of 'church' has undergone relatively little refinement since the early twentieth century, although the notions of 'house church' and 'megachurch' were developed in the 1980s. Similarly, little progress has been made in applying or refining the closely related concepts of 'ecclesiola in ecclesia,' 'fraternitas,' and 'religious order' that Joachim Wach (1898–1955) and others had elaborated. Instead, the late twentieth century saw the development of other concepts designed to capture the organizational forms taken by Christianity in Sub-Saharan Africa, Latin America, and the former Soviet Union. They included 'independent churches,' 'African initiated churches,' 'base ecclesial communities,' and 'underground churches.' But in North America greater analytical attention was given to 'denominations' and their constituent 'congregations' at the local level. Research has centered on the social and ethnic patterning of denominations, the conditions favoring schism and merger, the ambiguous status of theological seminaries, the position of female clergy, the complex webs of 'interorganizational fields' in which denominations operate, the polarization of conservative and liberal factions and the associated threats to denominational integrity, the growth of special purpose groups, and tensions between religious hierarchies and functional agencies (Chaves, 2004; Ammerman, 2009; Roozen, 2011). Another rich vein of research has investigated the contribution of denominations toward ideologies of pluralism, pluralistic provision of social welfare, social movement campaigns, and the Third Sector of community and voluntary work (Chaves and Tsitsos, 2001). There is also strong evidence of growing isomorphism between the structures of religious organizations involved in social service delivery and the dominant forms of nonreligious, not-for-profit organizations – no doubt partly as a consequence of

tax codes that 'flatten out' differences between all tax exempt organizations.

The study of religious organizations has developed more slowly in relation to religions that are less formally structured than are most Christian organizations. Thus, although the authority structures and principles of membership may be less formal than in Christianity among indigenous spiritualities, popular religiosity, and religious traditions such as Buddhism, Hinduism, Islam, Jainism, Judaism, Sikhism, Taoism, and Shintoism, they nevertheless have distinctive forms of organization. For example, Muslim organizations in Muslim-majority countries as well as in the countries of Western Europe, Australasia, and North America where growing numbers of Muslims are living as both migrants and settlers include 'brotherhoods,' mosque committees, seminaries, '*biraderi*' (clan networks), and '*waqf*' (charitable endowments). Similarly, Buddhist monastic institutions (*sangha*) and transnational movements of 'engaged' or 'compassionate' Buddhism have adapted to widely differing cultural, social, and political circumstances (King, 2009). Moreover, Hindu movements actively promote their values through transnational programs of school-level education and political mobilization. Yet, research has also underlined the extent to which the organization of non-Christian religious activities in Europe, North America, and Australasia is increasingly following the path of denominationalization on the basis of local groupings that closely resemble congregations (Yang and Ebaugh, 2001).

Dynamics of Religious Organizations

The confluence of two intellectual developments beginning in the 1950s helped to stimulate new studies of organizational dynamics in religions. One was the growing salience of 'organization theory' in social sciences, and the other was a concern with 'ministry' as a modern profession in religious organizations experiencing rapid social change (Beckford, 1973). Although studies of religious organizations made relatively little impact on organizational theories in general they chimed well with emerging interests in organizational climate and culture in the 1970s. They also overlapped with newsworthy research on communes and social movement cultures which highlighted the importance of strong commitments and normative beliefs. Subsequent findings about the importance of rituals, retreats, and emotion management in all kinds of organizations only enhanced the interest that religious organizations came to have for organizational analysts (DiMaggio, 1998). The rapprochement between the study of formal organizations and the study of religious organizations was further boosted in the 1980s when so-called New Age and quasireligious and parareligious businesses began to attract attention for trying to combine profit-seeking activity with ethical and religious practices. 'Selling spirituality' (Carrette and King, 2005) has also elicited skepticism and criticism.

Indeed, general questions about the resourcing of religious organizations do not figure as prominently in research as they should. Competition for members and the material resources that they bring to religious groups is a feature of societies such as the United States and Japan where segmented markets exist within the broad categories of Christian, Buddhist, and Shinto organizations. In many other countries, however, 'religious markets' are much less vibrant except among the new or marginal movements which compete for immigrants or drop-outs from the locally dominant religions. Rates of 'switching' between religious organizations also vary widely between countries or regions with different degrees of competition between a monopoly, majorities, pluralities, and minorities.

The economic underpinning of religious organizations is no less varied than are their other characteristics. Some organizations such as the Catholic Church and the Orthodox Church in parts of Central and Eastern Europe have acquired substantial amounts of land, property, and wealth over the course of centuries. Others such as Buddhist organizations in Asia possess priceless buildings and artifacts. Meanwhile, the assets of some of Islam's charitable foundations and brotherhoods contribute strongly to local economies. The generation of economic resources can therefore take many different forms, although variants on 'enrollment economies,' 'freewill offering,' and tithing are widespread. Moreover, the tax systems of some states confer fiscal advantages on religious organizations.

But very few large religious organizations – unlike their secular counterparts – engage in outsourcing or subcontracting their central operations to other suppliers. The main reason for this is that it would be difficult for religious organizations to protect their all-important sense of ideological or theological integrity if they had to depend on agencies outside their control. In extreme cases, sectarian and communal organizations that insist on distancing themselves from 'the world' may choose to make their own furniture, grow their own food, make their own clothes, and print their own publications. By contrast, the revenue of other religious organizations can come from the sale of products and services to the public, including access to sites of pilgrimage and worship, the provision of healing rituals, and the conduct of rites of passage. Indeed, such organizations also enter into contracts with suppliers of, for example, sacred artifacts, *kosher* or *halal* food, musical instruments, and ritual clothing. But controversies tend to engulf those newcomers to the religious marketplace which solicit direct donations from the public, encourage followers to make bequests and legacies, or charge fees for participation. Equally controversial is the fact that some religious organizations expect their members to work for them without payment and without sickness or retirement benefits.

Two dimensions of religious organizations are crucial for their dynamics: authority and leadership. This does not mean that other dimensions are unimportant but it signifies that organizations purveying allegedly sacred truths and the highest values show a disproportionately strong concern with establishing, reproducing, and defending their teachings and practices against perceived corruption, subversion, or apathy.

Authority

Not only are religious organizations in competition with purveyors of rival versions of ultimate truths but they also have to monitor and regulate their own members or followers in order to deter heresy, apostasy, and abuse. This is why questions of authority are crucial for religious organizations and why change

often meets with strong resistance. Religious organizations are therefore distinctive, if not unique, for the effort they put into preserving and elaborating the connections between their founding truths and their organizational structure. The authority of leaders depends heavily on their success in constantly rehearsing these connections in rituals, symbols, exegesis of sacred texts, preaching, praying, teaching, and meditating.

Difficulties can occur, however, in religious organizations that have a division of labor between a clerical hierarchy and a parallel set of agencies responsible for the management of finances, property, human relations, publishing, education, and healthcare. The delivery of welfare services by faith-based initiatives in some religious organizations is a further source of potential difficulties, especially if it exacerbates tension between local groups and central bureaucracies. Competing sources of authority between these different organizational structures can generate friction and conflict. Nevertheless, religious organizations remain more numerous and more active than any other American nonprofit organizations in providing social services (Cadge and Wuthnow, 2006).

Sources of Authority

Christianity has taken many organizational forms that are unique among the world's religions not only for being highly centralized and formal but also for cutting across ethnic, tribal, and political groupings. Indeed, some churches in medieval and early modern Europe operated as part of the machinery of state. By contrast, Hinduism, Judaism, and Shinto crystallized slowly out of predominantly caste-based, tribal, and ethnic cultures, thereby giving rise to temples, synagogues, and shrines as the locations for rites and ritual worship rather than as agencies of civil administration. Diasporic Judaism, lacking the central authority previously vested in the Temple at Jerusalem and its hereditary priesthood, regrouped around rabbis as teachers of the law and around synagogues as ritual centers. Communal organizations continue to play a major role in preserving the ethnic and religious identity of many Jews, but would-be central agencies for controlling Jewish beliefs and practices do not command universal compliance.

Buddhism and Islam both emerged from deliberate attempts to cultivate philosophical and religious systems that were partly at odds with their social context but they have also formed close alliances with states and political powers at various times. Buddhism in Japan and Thailand, for example, has sometimes functioned through parish systems. Since 1945 massive, hierarchical movements of lay Buddhists such as Reiyūkai, Risshō Kōseikai, and Sōka Gakkai have flourished in Japan. In many regions of Asia, large-scale and well-organized movements of 'compassionate' or 'engaged' Buddhism are currently mobilizing their followers in campaigns for justice, peace, and environmental sustainability (King, 2009).

The organizational forms of Islam are subtle, multistranded, and variable by region of the world. Although Islam lacks a centralized authority structure, it can be effectively interwoven with states, political parties, and liberation movements. Indeed, the complex organizational tapestry of Islam consists of multiple – and sometimes competing – sources of theological, legal, spiritual, political, and moral authority. The authoritative figures include learned experts, jurists, hereditary sheikhs, leaders of brotherhoods, and clergy (among the Shi'ites). Now that tens of millions of Muslims from different national and ethnic backgrounds live as religious minorities in North America, Australasia, and Europe, some governments have encouraged the formation of representative bodies of Muslims that could help to resolve questions about, for example, the licensed slaughter of animals for meat, the provision of burial spaces, and the management of Muslim chaplaincies in hospitals, prisons, and military institutions.

Forms of Governance

The implementation of religious authority in forms of governance can take many different forms in religious organizations. At one extreme are loosely structured fellowships, and at the other extreme, are large, complex, and formal organizations which require their members to accept centrally imposed dogmas and practices mandated by leaders. Most religious organizations fall on a continuum between these two extremes, although their precise location may change in response to internal or external factors. The time-honored distinction between church-type and sect-type organizations is no longer a good guide to these variations in degrees of complexity, centralization, and formality.

Differences among Orthodox, Episcopal, Presbyterian, and Congregational forms of governance reflect differing interpretations of Christian scripture. Similarly, the distinction between the authority exercised by ordained clergy, monks, and nuns in religious orders, and laity has theological justification. But social scientific research examines how well the official authority structures actually inform the actions of members of religious organizations and how far external factors shape organizational cultures. For example, the Episcopal form of governance is interpreted and implemented in widely differing ways in churches in the worldwide Anglican communion. Presbyterian and congregational forms of governance have also come under pressure to adapt their exercise of authority to the sociocultural norms and values prevailing in different societies. In particular, critics of patriarchalism have effectively challenged the gendered distribution of authority in churches and tried to infuse them with feminist, antihierarchical values (Nesbitt, 1997). Moreover, tension between congregational autonomy and pressure to conform to the authority at the regional and national levels of religious organizations is common.

Fundamentalism

Questions about religious authority have dominated analyses of the forms of religious fundamentalism that became influential in various faith traditions in the closing decades of the twentieth century. Fundamentalism centers on unswerving faith in the authority of fixed principles, usually enshrined in sacred texts, to dictate categorical rules for the conduct of personal and public life. It is also associated with assertive leadership and deep distrust of life outside its groups of committed believers. Christian fundamentalism thrives in local congregations, religious broadcasting media, online networking, and social movement campaigns against, for example, abortion and gay

rights. The 'vehicles' of Islamic fundamentalism also include the full gamut of new communications technologies, especially dedicated websites, as well as conservative institutions of Islamic learning. Hindu fundamentalism is closely associated with the political mobilization of resources in India and in diasporic communities in support of Hindu nationalism. Fundamentalism is not, therefore, antimodern, traditionalist, or otherworldly. On the contrary, it seeks to transform the world in accordance with its reading of authoritative texts, and this is compatible with forms of organization that are effective, flexible, and responsive to local contexts.

Leadership

Roles

Religious organizations vary widely in their leadership roles, structures, and training (Hoge, 2009). Ideas about the source and nature of sacred power shape the precise pattern of roles at all organizational levels. Leaders of organizations that identify sacred power exclusively with scriptures and laws derive their authority mainly from their acquired capacity to read and interpret them. Scholars, teachers, and jurists exemplify this pattern of leadership in Judaism and Islam. The various forms of priesthood that are characteristic of Hinduism, Shinto, Christianity, and Sikhism combine reverence for sacred texts with belief in the capacity of priests to perform rituals allowing human beings to interact with divinities and sacred power. The effectiveness of this power is believed to be conditional on the proper conduct of rituals by priests. In contrast, prophets and charismatic leaders are more likely to aim at reforming religions by opposing their institutionalized practices and seeking to replace them with radically new beliefs and practices. Different again is the position of ministers in many Protestant traditions whose leadership consists mainly of preaching, exposition of scripture, pastoral care, and – at least in evangelicalism – efforts to persuade followers of their sinfulness and need for redemption. Some other religious traditions have 'virtuosi' such as monks, nuns, and 'holy men' who exercise leadership on the strength of their discipline, asceticism, devotion, and selflessness. For example, the *sangha*, or monastic community, remains at the heart of Buddhism in many parts of the world; monastic institutions were the bulwark of Christianity in the early European Middle Ages; Catholic religious orders have been in the forefront of missionary work in Africa, Asia, and Latin America; and monks continue to occupy the highest leadership positions in some Orthodox churches. But strong notions of religious leadership tend to meet resistance in traditions that locate authority in the spiritual freedom of individuals to find their own way to the sacred, sometimes under the guidance of spiritual masters, teachers, or gurus.

Although the founders of some new religions in Japan, of spiritist movements in the Caribbean region and Central America, and of new spiritualities in the West have been women, the pattern in many religions is either to exclude women from positions of leadership or to prevent them from gaining access to the highest positions. The ordination of female priests and the consecration of women bishops have been highly contentious in the worldwide Anglican communion. Pressure to admit women to the Roman Catholic priesthood has been mounting since the 1960s when a shortage of priests became apparent in western countries, and large numbers of nuns began to leave their orders and their work in schools, orphanages, and hospitals.

Local Settings

Religious leaders are usually attached to particular buildings or social centers where they conduct teaching, preaching, meditation, worship, prayer, or pastoral functions. Some also have spiritual oversight of institutions such as schools, Sunday Schools, youth organizations, seminaries, orphanages, hospitals, refuges, pilgrimage sites, prisons, and military establishments. Many Christian organizations deliver religious, pastoral, and welfare services in geographical areas known as parishes representing the local units of national or international churches. The idea that residents of a locality would belong to its parish and form a congregation of worshippers under the leadership of local clergy was especially widespread in parts of Europe where the dominant church was closely aligned with the state. Japanese Shinto also has a system of parishes linked to local shrines.

Congregations

Congregations, as the basic unit of most Christian organizations, are the social groups with which members identify most strongly (Ammerman, 2009). Their precise status varies with the theology and authority structure of the broader churches or denominations to which they belong. The congregations of hierarchical churches are local outlets of ideas and practices controlled by regional, national, and international authorities such as bishops, archbishops, cardinals, and the Pope. By contrast, local congregations in religious organizations with little or no theological justification for hierarchy or centralized control tend to enjoy relative autonomy. Examples include independent fellowships of conservative Protestants, the Reform Synagogues of Great Britain, and the Christadelphians. The balance between centralization and local autonomy in religious organizations is an important determinant of their capacity to generate resources, mobilize members, deliver services, respond to internal problems, and influence public life.

As Hinduism, Islam, and Sikhism have never been structured in the regions of the world where they originated in the form of inclusive, unitary organizations, their local groups have not tended to function as congregations or parishes. Although temples, mosques, and gurdwaras undoubtedly operate as ritual and pastoral centers for people in their vicinity, it is rare for them to be strongly integrated into higher-level structures. They are accountable to their private owners or to their management committees. Consequently, local groups select and retain their religious leaders as professionals or qualified volunteers rather than as employees or agents of religious organizations at a higher level.

Nevertheless, the growing numbers of Hindus, Muslims, and Sikhs now residing in Europe and North America are adopting forms of organization that more closely resemble Christian patterns of denominations and congregations (Yang and Ebaugh, 2001). Their increasing involvement in chaplaincies in healthcare, military, and prison establishments is another

indication of their ability to adapt their organizational forms to local contexts.

Recruitment and Training

The major Christian churches and denominations in advanced industrial societies are experiencing varying degrees of difficulty in recruiting and retaining their clergy (Carroll and McMillan, 2006). At the same time, the social characteristics of recruits have also changed since the mid-twentieth century: women are now much more numerous; a career in the clergy is a second career for a growing number of recruits; ethnic diversity is more apparent; and some churches actively seek recruits from developing countries. But despite the 'feminization' of religious leadership (Nesbitt, 1997), the upper echelons of many churches are still under the control of men.

It is mainly in the economically developing countries of Africa, Asia, Eastern Europe, and Latin America that the supply of young women and men for Christian ministry training remains relatively buoyant. It is no accident that these regions of the world are also those where participation in churches and denominations has also been increasing strongly in recent decades. Similarly, the production of religious scholars and imams in *madrassas* in the heartlands of Islam in the Middle East, North Africa, and Asia has expanded to meet the demand for qualified men to serve in the growing number of mosques and chaplaincies in Europe and North America. Globalization affects religious organizations no less powerfully than other kinds of organization.

Questions About the Future

Religious organizations – notably the Roman Catholic Church – were among the major contributors to the emergence of civil society at the international level in the nineteenth century. Indeed, religious international nongovernmental organizations (RINGOs) still constitute one of the largest categories of lobbyists at the United Nations. Recognition of the important roles played by religious organizations in articulating, aggravating, and solving international problems has increased sharply since the 1980s. But it remains to be seen how the growing strength of China, India, and Indonesia in international politics and economics will affect the balance of power among the RINGOs.

A closely allied issue for the future arises from the fact that processes of globalization have fostered the growth of Buddhist, Hindu, Muslim, and Sikh organizations in the liberal democracies of Western Europe, North America, and Australasia – as well as in the regions of the world where they had long been powerful. Transnational religious movements continue to play leading roles in establishing the organizational infrastructures for the practice and the promotion of Buddhism, Hinduism, Islam, and Sikhism. At the same time, agencies of the state have responded to these developments with varying degrees of enthusiasm. One of the questions for the future is, therefore, how well these recently implanted religious organizations will adapt to their legal, political, and cultural circumstances. Another question is whether their forms of organization will follow the logic of isomorphism with other organizations in the voluntary sector of their respective civil societies. A third issue is about their prospects for influencing the organizational forms of Buddhism, Hinduism, Islam, and Sikhism – and other religions – both in their countries of origin and in their countries of settlement.

Finally, religious organizations in the West seem increasingly likely to be affected by legal issues arising from the growth of religious diversity occasioned mainly by globalization. The implementation of international codes of human rights and of domestic laws against discrimination on the grounds of religion (or in protection of religious freedom) increasingly encounters the objection that there must be limits to the accommodation of religious diversity. The very understanding of 'religion' is germane to many legal cases concerning the right to manifest or to practice religion in public. As a result, the eligibility of religious organizations for tax privileges, for involvement in public education, and for the status of contractors to public authorities is increasingly at stake in legal disputes. For example, chaplaincies in the military, prisons, and hospitals have become sites of contention not only for the advocates of religious freedom but also for secularist opponents to any form of official recognition or resourcing of religious organizations.

Remedies and Damages: Legal Aspects

Theodore Eisenberg, Cornell University, Ithaca, NY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Damages levels vary across countries. The size of damages awards in the United States became an issue of debate stemming from asserted civil liability crises. Little evidence exists that damages awards have substantially increased over time and one longitudinal 40-year data set shows no real growth over four decades. Punitive damages in the United States may be the most controversial area of damages. The best available evidence is that punitive damages awards are infrequent: punitive damages are requested in about 10% of completed trials and awarded in about one-third of the cases in which plaintiffs won and they were requested. Growth in punitive damages award levels has not followed a clear trend. The relation between punitive and compensatory awards is highly statistically significant, contrary to claims that punitive damages amounts are random.

Remedies can be categorized as monetary or nonmonetary. Although much litigation leads to monetary awards, many cases end without a monetary award. Injunctive relief, orders to specifically perform contracts, divorce decrees, probate of wills, and other orders do not necessarily involve damages or monetary payments.

Nonmonetary Relief

Several categories of nonmonetary relief exist and their use varies across countries. For example, three different approaches exist to the availability of specific performance – a particular act that a party is ordered to perform by a court – for contract breach: (1) some countries, such as Germany and socialist systems, make specific performance generally available, subject to exceptions, (2) other countries, such as France, make specific performance available for specific obligations, while (3) common law countries, including England and the United States, regard specific performance as an exceptional remedy, available only in limited circumstances. In the United States, evidence exists that sophisticated parties often contractually provide for specific performance (Eisenberg and Miller, 2014).

Nonmonetary relief to prevent injury can be more important than redressing injuries already done. Common law countries address this need by allowing injunctive relief in cases in which irreparable harm can be demonstrated. Other legal systems, such as Germany, Switzerland, Austria, and others influenced by German law, have a general class of actions to prevent threatened injury. Courts in such systems have less discretion to deny preventive remedial relief than do common law courts. Some systems allow remedial relief but lack a coercive component, such as a penalty for violating an injunction, to enforce it (Stoll, 1983). Prejudgment nonmonetary remedies, such as attachment and preliminary injunction or its equivalent, are widely available.

Damages Rules across Countries

With respect to monetary relief, one cannot completely separate the question of the quantum of damages from the question of liability. The English jurist William Blackstone (1723–80), in writing about the common law, did not regard damages as a separable ending of the legal process. The right to damages arose the instant the victim was injured. Nevertheless, one can intelligently address many damages issues independently of the question whether any damages should be awarded.

In the last quarter of the twentieth century, damages issues became a focus of the tort reform movement in the United States, alarming foreigners doing business in the United States. In many respects, however, damages rules are not strikingly different between the United States and other countries. All countries seek to compensate victims fully, though most depend more on social compensation systems than does the United States. Most countries allow consideration of the injured person's fault, a consideration similar to the United States doctrine of comparative negligence, and a few (the Netherlands and Sweden) allow for mitigation of damages in view of the parties' financial circumstances and insurance coverage. European and Japanese damages rules governing injury, though less feared than United States rules, are not necessarily simpler. They have been said to contain confusing variation both in the constituents of noneconomic damages and in measuring them (Pfennigstorf, 1991).

There are, however, differences in the size of awards. Non-United States systems produce lower and more predictable within-country awards. Some of this predictability stems from written and unwritten guidelines. In Japan and Sweden, for example, expert commissions establish consistent guidelines for automobile accidents. Sweden extends this practice to injuries caused by medical mistreatment, by pharmaceutical drugs, and by environmental pollution. Some of the perceived award consistency may be due to the absence of studies. For example, 38%–59% variation in Austrian awards for pain and suffering has been reported based on the valuation methodology courts use (Flatscher-Thöni et al., 2013). Across European countries, awards are not consistent. One study estimates that in a wrongful death case involving a 20-year old victim with no dependents, awards across the European Union would vary from £176 368 in Italy to £1250 in England; it also finds that pain and suffering awards vary considerably across countries (McIntosh and Holmes, 2003).

Social Scientific Study of Compensatory Damages

Media reports, which understandably emphasize extreme awards, promote exaggerated perceptions of large United States damages awards. The media overreport products liability and medical malpractice cases, exaggerate plaintiff win rates, and distort impressions about the actual distribution of jury awards. In addition, special interest groups that seek to minimize the liability of large corporations promote inaccurate descriptions of the legal system that reinforce the media's tendency to emphasize large recoveries. Interest groups such as the US Chamber of Commerce and the American Medical Association exaggerate the impact of damages awards and the legal system's effect on primary actors' behavior (Eisenberg, 2009). Social scientific assessment of damages is critical in helping to ameliorate the effect of both the media reporting tendencies and the effect of interest groups' exaggerations.

General Adequacy of Damages

Despite agreement that awards are higher in the United States, little evidence exists to support the claim that injury victims are systematically overcompensated in any country. For example, in the United States, evidence exists that plaintiffs with small losses tend to be overcompensated but plaintiffs with large losses tend to be undercompensated (Vidmar, 1998). An English study found that serious injuries may not result in substantial recoveries and that minor injuries that do lead to recoveries may have unexpectedly severe consequences (Law Commission, 1994). Both findings suggest systematic undercompensation. Evidence from medical malpractice studies establishes underdeterrence of negligent behavior by hospitals and physicians (Mello et al., 2007). The massive scope of medical malpractice has not materially diminished over time (Landrigan et al., 2010; National Health Care Quality Report, 2007; National Health Care Quality Report, 2009).

Award Levels and Trends

The most studied system of damages is the tort system in the United States. Concerns about the level of awards, time trends in awards, and the relative competence of judges and juries have generated several studies. Data gathered by the National Center for State Courts from 45 of the largest 75 United States counties, under grants from the Bureau of Justice Statistics (BJS) (1995, 1999, 2004, 2008), provide the least biased sample of awards in litigation. The data allow for meaningful comparisons across case categories. Moreover, since the same 45 counties were surveyed in 1991, 1996, 2001, and 2005 (with 110 additional small counties surveyed in 2005), the data also allow meaningful comparisons over time. **Table 1** summarizes the pattern of jury and judge compensatory damages awards for the combined BJS data sets, in thousands of 2005 dollars by case category and by trial mode (judge or jury).

Table 1 Mean and median compensatory damages award, state court trials, by case category trial mode, 1991–2005, in thousands of 2005 dollars

Note: Unweighted results reported.

Table 1 shows that damages awards vary substantially by case category. Median compensatory damages awards are highest in cases involving products liability and medical malpractice. Median awards in these case categories are substantial multiples of the median award in automobile accident cases. The levels of awards are generally modest and are consistent with other comprehensive studies of particular jurisdictions.

Reliability of Compensatory Awards

In studies that include independent assessments of the defendant's behavior, damages awards correlate with the nature and degree of the wrong. Studies of medical malpractice cases show that those who behaved the worst and caused the most harm are likely to pay damages and likely to pay the most damages (Cheney et al., 1989; Cranberg et al., 2007; Farber and White, 1991; Peeples et al., 2002; Sloan et al., 1993; Spurr and Howze, 2001; Taragin et al., 1992). Studies of securities law cases also find that case outcomes correlate with the merits of claims (Cox et al., 2008). Experimental studies confirm these findings (Wissler et al., 1999). Osborne (1999) uses a different methodology but reaches similar results. His study includes many substantive areas of law and examines the relation of court awards to the pretrial expectations of litigants and their attorneys and to measurable, economically relevant damages. He finds that court awards are highly predictable, as variance in expectations explains much of the variance in awards. The awards also significantly relate to both medical costs and property damage. He rejects the hypothesis of a highly unpredictable court system.

Compensatory Damages Awards – Time Trends

Table 2 allows study of award trends over time. A popular perception exists that damages awards increase substantially over time, and some empirical studies support the claim. But these studies have been questioned on methodological grounds (Vidmar, 1998). Table 2 shows little systematic evidence of increasing trial awards. A 40-year longitudinal study of awards within a jurisdiction showed no real increase in award levels over time (Seabury et al., 2004).

Table 2 is limited to state court cases. Awards in federal court cases tend to be higher, at least partially because of jurisdictional amount requirements in federal court. Median trial awards in federal court products liability cases did increase from the early 1980s to the mid-1990s. The increase also occurred in judge-tried cases and in contracts cases.

Table 2 Mean and median compensatory award 1991 to 2005, state court trials, in thousands of 2005 dollars

Total	829	50	12 098	207	29	4051

Note: Unweighted results reported.

Punitive Damages

Punitive or exemplary damages are sometimes awarded in addition to the monies given to make the victim whole. But normally punishment is left to the state, not to private civil litigation. Thus, many legal systems do not allow damages beyond those necessary to compensate the victim. For example, little authority to grant punitive damages exists in Roman law and in some of the continental European systems that derived from it. But many countries allow punitive damages or their equivalent (exemplary damages, moral damages) in some classes of cases. Recently, the European Court of Justice has ruled that national courts must be willing to award exemplary damages pursuant to claims or actions founded on European Community law, if such damages may be awarded pursuant to similar claims based on domestic law. Nevertheless, punitive damages are substantially less important outside the United States.

The most discussed questions in the recent United States literature on damages relate to punitive damages. Understandably skewed media coverage emphasizing high awards, combined with advocacy by lobbying groups, has generated enormous pressure on punitive damages law and has helped to shape professional and public impressions. Business lobbying groups have enjoyed some success, with several states enacting provisions raising the burden of proof for punitive damages claims, placing monetary ceilings on awards, and otherwise limiting the likelihood and size of punitive awards.

Social science research on punitive damages expanded as a result of the 1994 jury award of $5 billion in punitive damages against Exxon Corporation (now Exxon Mobil) for the 1989 Exxon Valdez oil spill. Exxon-funded several leading academics, which produced an impressive body of work that is critical of punitive damages and supports 'reform.' But some of the work is inconsistent with prior theoretical discussions of punitive damages (Eisenberg, 1998; Vidmar, 1998), some of the work is methodologically unsound (Eisenberg and Wells, 2006), and none of the work seeks to reconcile its claims of incoherent punitive damages awards with real-world evidence of their coherence (Eisenberg et al., 2002). In 2008, the United States Supreme Court reduced the punitive damages award to $500 million but expressly refused to rely on the social science research funded by Exxon and noted that claims of out-of-control punitive damages awards were refuted by empirical evidence (Exxon Shipping Co. v. Baker, 2008).

Rate of Punitive Awards

Several large studies of punitive damages awards, such as Moller (1996), Daniels and Martin (1995), data commissioned by the BJS (1995, 2004, 2008), and Eisenberg et al. (2006), cover multiple United States jurisdictions and include case categories that are sufficiently well defined to warrant comparison. Each of the sources reveal overall punitive damages award rates of less than 10% in successful jury trials. In two of the areas of greatest interest to policymakers, products liability and medical

Table 3 Mean and median punitive award 1991 to 2005, state court trials, by trial mode, in thousands of 2005 dollars

	Mean	*Median*	N	*Mean*	*Median*	N
Year	*Punitive award, juries*			*Punitive award, judges*		
1991	749	702	177			0
1996	2418	65	121	743	39	55
2001	6980	83	155	169	55	48
2005	2967	147	141	251	38	45
Total	3241	83	594	407	47	148

malpractice litigation, punitive awards are especially rare. Except in case categories dominated by fraud and employment law issues, all punitive award rate levels are likely less than 10%, and many are less than 5%.

For example, in the BJS data from 2005, punitive damages were sought in about 10% of the cases that reached trial, and were awarded in about 30% of the cases won by plaintiffs in which they were sought (Eisenberg et al., 2011). These social scientific analyses undermine the belief that punitive damages are frequently awarded.

Level of Punitive Damages Awards

Large, publicized punitive awards, such as that against Exxon, create the impression that punitive awards are on average much larger than they truly are. BJS data allow one to assess the level of punitive damages awards. Table 3 summarizes punitive damages awards, in thousands of 2005 dollars, for the years 1991, 1996, 2001, and 2005. Median punitive damages awards have been more modest than the headline-grabbing awards. Mean punitive awards are substantially affected by extremes. Excluding the most extreme punitive award in the 1991 and 1996 reduces the mean by over 25% in one year and by over 50% in the other. All studies confirm that the bulk of punitive awards are modest.

Relation between Punitive and Compensatory Awards

A criticism of punitive damages is that they bear no relation to the compensatory award – the punishment inflicted therefore is not proportional to the harm caused. The United States Supreme Court has indicated that a punitive damages award normally should bear a reasonable relation to the compensatory award. Social scientific analysis suggests that punitive awards do relate to compensatory awards. Figure 1 shows the relation (in logs) between compensatory and punitive awards in the BJS studies, by year and adjudicator. It shows an unmistakable correlation. The constancy of the relation indicates that the pattern is not a consequence of cases in a particular year or of cases tried before a particular adjudicator.

Figure 1 The relation between punitive and compensatory damages over time, by adjudicator.

Punitive damages awards are thus rarer, smaller, and more closely related to compensatory awards than is widely believed.

Punitive Damages Awards – Time Trends

Punitive damages, like compensatory damages, are often said to be ever increasing in number and size. The BJS data allow one to compare the rate and size of punitive awards. Table 3 above shows that median punitive awards were substantially lower in 1996 than 1991. Mean awards were higher in 1996, an increase that is a function of a few large cases. Median awards increased from 1996 to 2005 but mean awards first increased and then decreased. Overall there is no consistent pattern of increase. Table 3 also shows no evidence of consistent increases in the frequency of punitive damages awards over time. Thus, even minimal social scientific analysis provides no support for the belief that punitive damages awards are ever increasing in size or frequency.

The Importance of the Adjudicator

It is widely believed that the choice of adjudicator – judge, jury, arbitrator – substantially affects the damages awarded. Higher and more variable awards in the United States are attributed to the greater role of jurors as adjudicators. While real differences exist across adjudicator groups, the social scientific evidence supports skepticism about claims of massive differences across adjudicators. The classic Kalven and Zeisel study used questionnaires to presiding judges in about 4000 actual civil jury trials in the 1950s (Kalven and Zeisel, 1966). Their data showed a 78% agreement rate between judge and jury on liability, with no revealing pattern in the cases of disagreement. The rate of judge–jury agreement is high compared to other human endeavors. They also showed that jurors awarded on average 20% more than judges said they would have awarded. The modest judge–jury differences reduced interest in attacks on juries.

Renewed attacks on the jury's competence to assess damages, and especially punitive damages, reemerged in the 1980s and 1990s. Research using interviews and experiments find that different decisionmakers are quite similar and predictable with respect to their judgments of injury severity (Wissler et al., 1999). Such research also finds that jurors' awards lose consistency in translating severity of injury into dollar awards. Other studies suggest somewhat lesser judge–jury differences. Vidmar and Rice (1993) report results of experiments in which subjects were jurors awaiting jury duty and legal professionals. The outcome of interest was the level of pain and suffering awards. In a medical malpractice burn case, they found that six-person juries would give more variable awards than 12-person juries but that both groups would be less variable than individual legal professionals. Their second experiment involved an automobile accident case and a medical malpractice case. They found no differences between jurors and legal professionals.

Studies of actual cases, which lack the controls of experimental settings but provide the relevant setting, suggest modest adjudicator differences. Osborne's (1999) study compares the predictability of judge and jury awards based on litigant expectations. He finds that one can reject the hypothesis that jury trials are largely random events. Litigant expectations explain more than a third of the variance in awards. And he finds that the behavior of judges is not significantly more predictable than that of juries. Helland and Tabarrok (2000) conclude that most differences between judge and jury awards can be explained by differences in the sample of cases coming before judges and juries but that some suggestive differences exist. Eisenberg et al. (2006) find little meaningful difference in the pattern of judge and jury punitive damages awards.

Exxon-funded research finds experimental evidence of vast judge–jury differences. For example, Hastie and Viscusi (1998) report mock jurors to be much more likely than judges to impose punitive sanctions in a hypothetical railroad accident case. Vast judge–jury differences on liability in these studies, which contrast with Kalven and Zeisel's and other findings, calls into question the experimental designs' ability to detect socially meaningful punitive damages differences between judges and juries.

Overall Assessments and Comparisons of Damages Awards

Greater injuries lead to greater damages awards in all systems for which data are available. With respect to variability in the United States, where variability is regarded as greatest, from half to almost three-fourths of awards' variation can be accounted for by measures of injury severity, as well as by other predictors, but a substantial random component also exists. Legal systems that rely on schedules of damages for various injuries have lower variability though not necessarily more complete compensation.

Prospects for definitive social scientific comparison of damages rules' operation are dim. Some inherent limitations apply to comparing performance of legal rules across state and national boundaries. The number of differing legal systems will tend to be small – there are, for example, only 50 states, and gathering useful damages information about that many countries is an enormous task. Important differences, such as varying reliance on social compensation systems, different mixes of cases reaching court systems, different methods for compensating attorneys, and varying standards of living and purchasing power need to be considered. For the foreseeable future, reasoned analysis of data available for individual jurisdictions and informal comparison across jurisdictions will have to suffice in assessing performance of the damages component of remedial systems.

Abstract

Remote sensing is one of a suite of geospatial technologies that are having a growing impact in a wide variety of areas from commerce to science to public policy. The field of remote sensing evolved from the interpretation of aerial photographs to the analysis of satellite imagery, and from local area studies to global analyses, with advances in sensor system technologies and digital computing. Today remote sensor systems can provide data from energy emitted, reflected, and/or transmitted from all parts of the electromagnetic spectrum. Examples of applications of these data include population and demography studies, study of archaeological sites, energy studies using hydrological models, urban planning, environmental monitoring, environments, treaty enforcement, land use/land cover planning, weather forecasting, and agricultural production estimation, just to name a few. The material that follows provides a brief overview of the historical development of remote sensing, emphasizing the increasing complexity of platforms, systems, and tasks.

Remote sensing is one of a suite of geospatial technologies that are having a growing impact in a wide variety of areas from commerce to science in public policy. While remote sensing's origins and technological advance are an outgrowth of military and intelligence applications, commercial and scientific applications of the technology have been growing. The field of remote sensing evolved from the interpretation of aerial photographs to the analysis of satellite imagery, and from local area studies to global analyses, with advances in sensor system technologies and digital computing. Today remote sensor systems can provide data from energy emitted, reflected, and/or transmitted from all parts of the electromagnetic spectrum. These data can then be transformed into information products either by manual or machine-assisted interpretation and employed in an analytical or management decision-making context. Examples of applications of these data include population and demography studies, study of archaeological sites, energy studies using hydrological models, urban planning, environmental monitoring, environments, treaty enforcement, land use/land cover planning, weather forecasting, and agricultural production estimation. This article provides a brief overview of the historical development of remote sensing, emphasizing the increasing complexity of platforms, systems, and tasks.

The definition of remote sensing used here, provided by the American Society for Photogrammetry and Remote Sensing, is as follows:

> In the broadest sense, the measurement or acquisition of information of some property of an object or phenomena, by a recording device that is not in physical or intimate contact with the object or phenomenon under study; e.g., the utilization at a distance (as from aircraft, spacecraft, or ship) of any device and its attendant display for gathering information pertinent to the environment, such as measurements of force fields, electromagnetic radiation, or acoustic energy. The technique employs such devices as the camera, lasers, and radio frequency receivers, radar systems, sonar, seismographs, magnetometers, and scintillation counters.
> (Reeves et al., 1975)

[†] Deceased

What follows is a brief summary of various sensor systems within the context of an historical background of remote sensing, and a short discussion of the future of remote sensing with some reference to social and behavioral sciences.

Sensor Systems

Many systems are used to detect energy patterns, which provide information about the Earth's atmosphere, oceans, and land surfaces. These systems range from cameras in aircraft to advanced sensor systems in Earth-orbiting satellites. Most satellite remotely sensed data are acquired by sensor systems such as multispectral scanners, linear array devices, and synthetic aperture radar systems that operate in the visible, near infrared, thermal infrared, and microwave portions of the electromagnetic spectrum.

These remote sensor systems can be broadly categorized into passive systems and active systems. A camera is an example of a passive system as its film records light energy reflected from an existing source, the sun. Add a flash attachment to the camera and it becomes an active system, since it now provides its own source of illumination. Passive systems record solar radiation reflected from the Earth's surface. Data derived from passive systems such as multispectral scanners provide information on, among other things, land use, vegetation types, distribution and condition of landforms, soils, surface waters, and river networks. Active microwave (radar) systems are used commonly in geological and hydrological applications. Because active systems do not depend on reflected energy from the sun, they are able to acquire data during the day or night. In addition, because the atmosphere does not attenuate microwave radiation as much as shorter wavelength energy, radar systems allow data acquisition in cloudy and rainy weather. This ability to operate day or night, and to create images of the Earth's surface in spite of cloud cover, makes radar sensors particularly attractive tools for improving understanding of tropical and polar areas.

Thermal infrared data, which represent a record of emitted energy from surfaces, have been particularly useful in

monitoring fires and land surface moisture conditions and in improving understanding of volcanic and geothermal activity. Ocean surface temperatures are related to the dynamics of coastal waters and ocean currents. Over land, plant water stress induces changes in canopy temperatures, which can be detected by thermal sensors. Thermal imagery from satellites has been used to record the nighttime lights of the globe, thereby indicating the spatial distribution of population. Other remote sensing systems detect the earth's magnetic and gravitational fields; these tools are used extensively in oil and mineral exploration and more recently ground water storage. Employing imagery from more than one portion of the electromagnetic spectrum can increase the information derived from an analysis, and is typically referred to as multispectral image analysis. Analyses of such multispectral data can, if properly designed, increase both the quantity and quality of information for given applications.

Image Interpretation

Interpretation of remotely sensed data is part science and part art. Manual interpretation of remotely sensed data is fundamental to all image interpretation. Even with the ever-increasing sophistication of machine-assisted image interpretation software, people must ultimately label the feature or phenomenon being identified. Not all individuals have equal interpretive skills with respect to aerial photographs or images acquired by remote sensor systems. It is axiomatic, however, that the more one knows about the elements, techniques, and methods of image analysis the better an interpreter one will be. In addition, the more one knows about the systems that acquire the data one is interpreting and the subject or discipline area most closely related to the interpretation, the better an interpreter one will make. It is seldom that an interpreter uses only the information in the imagery being analyzed as the basis for an interpretation. Ancillary data in the form of interpretation keys, maps, diagrams, textual material, and other forms of site-specific literature often aid in interpretations. Fieldwork is also a key element in image interpretation, and the collection of what is termed 'ground truth' should be accomplished whenever possible. Such ground truth validation is now increasingly assisted by around the clock digital cameras mounted strategically at field sites.

Resolution

Resolution is at the core of the successful use of remote sensing data. Resolution, as typically applied by a user, normally involves the question 'can I identify what I need to identify on this imagery?' The answer involves the use of the term ground resolved distance (GRD). GRD is used to describe the smallest object that can be unambiguously identified on the ground given good object-to-background contrast. Object-to-background contrast is important here. While it may be possible to see white lines on a black road on one set of images, it may not be possible to see the same size white lines on a concrete stretch of the same road. Resolution is thus dependent upon many things.

Indeed, the level of matching between the spatial, spectral, and temporal resolutions of the measurements and needs of the investigation will determine the usefulness of the derived data/information. Spectral range and resolution as used here refer to the portion of the electromagnetic spectrum being used in the measurement. It must be appropriate to the questions being addressed, for example, thermal range for fire detection, visible or infrared for vegetation health and condition. Spatial resolution determines the level of detail that can be extracted concerning objects in a given scene. As a general rule, it must correspond to the sizes of typical objects that must be separately identified. A resolution of a meter or less is needed to identify a single tree, a resolution of 5 m for a single-family residence, a resolution of 50 m might be sufficient for identification of most agricultural fields in North America, while a resolution of 500 m to a kilometer may be enough for studying ocean surface features. A necessary compromise between area to be covered and ground resolution of the measurement must take into account the volume of data that will be generated by, say, a large area coverage – millions of square kilometers – using high resolution data – 1–30 m.

The frequency of the data acquisition must also match the natural frequency of change in the landscape and the physical, social, or cultural phenomena of interest. For traffic studies, time frames of minutes can be important. Hourly observations might be of interest for certain meteorological conditions. Daily observations may be needed for an assessment of plant evapotranspiration associated with irrigated agricultural crops, while observation once every year could be sufficient for land cover change assessment.

Geographic Information Systems

The synergy between geographic information systems (GIS) and remote sensing comes into play here. To be interpreted accurately, remotely sensed data are often supplemented with other data. Often, these ancillary geospatial data can be found or included in a GIS for analysis. But to be valuable in decision-making contexts, GIS data layers should be as up-to-date as is practical. Remotely sensed data are a key technology for updating many types of GIS data. Thus, when environmental planners, resource managers, and public policy decision makers want to measure, map, monitor, or model future scenarios in order to facilitate better management decision making, remote sensing is being increasingly employed within the context of a GIS as a decision support system.

Historical Development

In the most general sense, the field of remote sensing begins with the invention of photography. Joseph Nicéphore Niepce took the first photograph of nature in 1827. It is a picture of the courtyard of his home in the village of Saint Loup de Varenne, France, with an exposure time of 8 h. In 1829, Niepce and Louis M. Daguerre signed a partnership agreement to work on a practical method of taking photographs. Niepce had been working on what he called heliography, or sun drawing, and Daguerre on dioramas, which he constructed with the aid of a camera obscura. The process they pioneered was called direct

positive image. The result of their collaboration, called the daguerreotype, was finalized in 1839. Also in 1839, an Englishman named William H. Fox-Talbot and a member of the Royal Academy invented the calotype (from the Greek *kalos* for beautiful and *typos* for impression). Talbot's positive–negative process is essentially the same as that used today, yet at the time the images produced by the two processes were not comparable.

In 1858, Gaspar Felix Tournachon, also known as Nadar, a Parisian photographer and balloonist, took the first known aerial photograph from a captive balloon at an altitude of 1200 feet over Paris. During the late 1870s, German foresters used aerial photography taken from balloons to map and measure the aerial extent of tree species. This is an example of the earliest known application of both aerial photographic interpretation and photogrammetry (the science of making precise measurements from remotely sensed data).

The use of rockets to launch cameras first occurred in 1906 when Albert Maul launched a rocket propelled by compressed air that was equipped with a camera. The camera took a picture from an altitude of 2600 feet and the camera was then returned to the ground by parachute. In 1909, Wilbur Wright took one of the first photographs from an airplane in Centrocelli, Italy. By 1915, cameras devoted to aerial photography were being produced. World War One saw an explosion in the use of aerial photographs. During the Meuse Argonne Offensive some 55 000 aerial photographs were taken and delivered to Allied Expeditionary Forces over a 4-day period. During the war, thousands of photo interpreters were trained. These interpreters laid the groundwork for the applications of aerial photographic interpretation that began to expand after the end of World War One.

In the early 1920s, the first books and articles on the applications of aerial photo interpretation began to be published. Lee's (1922) *The Face of the Earth as Seen From the Air* 'shows familiar scenes from a new angle,' and contains chapters on mountain features, coastal mud flats, plains, and submerged landforms. Joerg's (1927) 'The use of the air plane in city geography,' published in the *Annals of the Association of American Geographers*, focused on the application of aerial photography for urban studies. In 1927, Bergen's 'Aerial surveys for city planning' came out in the *Transactions of the American Society of Civil Engineers*, and in 1930 the American Geographical Society published the work by Platt and Johnson, '*Peru from the Air*.' While providing a regional overview of the country, this work also focuses on archeological sites. Of a more general nature is the work by Fairchild (1927) in the May issue of the *Annals of the American Academy of Political and Social Sciences* entitled, 'Aerial photography, its development and future,' which discusses potential applications of aerial photography from highway planning to water supply management. During this period, however, by far the most attention was given to the uses of aerial photography in oil exploration, structural and engineering geological analyses, land feature mapping, and soils mapping.

In the late 1920s and early 1930s, agencies of the US Government began to make significant use of aerial photography for operational applications. At this time, the Agricultural Adjustment Administration began to systematically photograph farm and ranch lands across the entire United States. This use of aerial photography for documenting agriculturally active areas has continued at 5- to 10-year intervals. The program now called National Agriculture Imagery Program (NAIP) is mandated to acquire peak growing season 'leaf-on' imagery and deliver this imagery to US Department of Agriculture (USDA) County Service Centers in order to maintain the common land unit boundaries and assist with farm programs. The goal of NAIP is to collect 1 m imagery for the entire conterminous United States. The imagery is either natural color or 'four band' imagery, and is delivered in the year of acquisition. This historical record has been significant in many types of studies, particularly in legal actions where the documentation of land use and/or land cover conditions and changes through time are in question. At the same time, the US Forest Service began using aerial photography to document much of the nation's timber reserves. Similar studies began in other nations as well, notably Canada. The US Geological Survey began to photograph many areas of the country in order to make topographical and geological maps based upon photogrammetric techniques and interpretation. The Tennessee Valley Authority and other regional agencies began to use aerial photography for planning purposes, as did state and metropolitan planning agencies. The *Master Plan of Residential Land Use*, published in 1943 by the Chicago Planning Commission, was based largely on data interpreted from aerial photographs.

World War Two led to developments in aerial photography, with a special interest in new and higher resolution film emulsions and thermal infrared imagery. Kodak patented the first false-color infrared sensitive film in 1946. The 1950s saw developments in technology that allowed multispectral imagery to be taken. Thermal infrared and side-looking airborne radar systems began to be acquired by the US military. Around this time, research personnel at the US Office of Naval Research coined the term 'remote sensing' to cover the expanding range of sensor systems and technologies for acquiring images of the world around us. This was the same year that the Soviet Union launched Sputnik, the first Earth-orbiting satellite. Civilian use of remotely sensed data during this period produced some of the first studies on the application of aerial photography for population estimation.

As early as 1946, the US Government began to pursue an operational space-based imaging system when the US Air Force asked the RAND Corporation to explore the possibility of launching an object into orbit. An early experiment in satellite land remote sensing was conducted from the Explorer 6 platform in 1959. The synoptic images of Earth's weather patterns acquired by the Television and Infrared Observational Satellite, launched in April of 1960, captivated the American public and demonstrated the capability and necessity of earth observation from space. Also in 1960, the first experimental spy satellite, a component of what would later become known as the Corona Program, was launched and, shortly thereafter, classified as secret. These data were withheld from the public until 1995, when the imagery and documentation were released to the public under Executive Order 12951. In 1965, National Aeronautics and Space Administration (NASA) initiated the Earth Resources Survey (ERS) program. This early program sought to develop methods and applications for remote sensing. The Department of Agriculture researched the use of

remote sensing for geological, hydrological, geographical, and cartographical applications. In 1966, the Department of Commerce began to participate in the ERS program by establishing the Environmental Sciences Group within the Environmental Sciences Administration (the predecessor to National Oceanographic and Atmospheric Administration (NOAA)). Also in 1966, the Department of the Interior initiated the multiagency Earth Resources Observation Satellite program, which studied the potential of Earth-observing satellites for natural resources applications.

During the 1960s and into the mid-1970s, NASA and a number of other Federal Agencies focused a significant amount of attention on applied remote sensing research. This was, in part, aimed at justifying the need for civil land satellite remote sensing systems and cataloging the variety of fundamental and applied science questions that could be addressed by such systems. During this period, efforts began to develop computer-assisted image interpretation techniques. Results of these activities, and the state-of-the-art practice of remote sensing during this time period, are documented in the American Society of Photogrammetry's first edition of the *Manual of Remote Sensing* (1975), as well as other sources.

The first Earth Resources Technology Satellite (ERTS-1) was designed originally as a research tool. When it was launched in July of 1972, however, this satellite ushered in a brief era of emphasis by NASA on the demonstration of operational applications using this series of satellites. Through 1974, ERTS-1 (later renamed Landsat 1) transmitted over 100 000 terrestrial images covering 75% of the Earth's land surface. Between 1972 and 1978, major research efforts utilizing this new civil land remote sensing data were conducted in agriculture, forestry, water resources, and geology. Other notable regional-scale applications research in the 1970s included the Large Area Crop Inventory Experiment, Agricultural and Resource Inventory Surveys through Aerospace Remote Sensing, and the Western Snow Melt Application System Verification Test.

In 1975, Landsat 2 was launched and the Ford Administration approved budget appropriations for Landsat 3, which was launched in 1978. In March of 1979, President Carter announced the Administration's commitment to maintaining the continuity of civilian terrestrial satellite remotely sensed data and recommended the transition of the program to the private sector. This initiated the process of program commercialization that would come to fruition in the mid-1980s. In 1981, the Reagan Administration accelerated the pace of Landsat commercialization by essentially rejecting the Carter Administration's commitment to an operational civilian land remote sensing program and advocating the immediate end of government funding for the Landsat Program.

By the middle of the 1980s, it was clear that satellite remote sensing could provide globally consistent, spatially disaggregated, and temporally repetitive coverage of the land surface of the Earth. Landsat 4, with the first Thematic Mapper instrument, was launched in 1982. Higher spatial resolution multispectral imagery was now publicly available and could be applied by scientists and professionals to the assessment of terrestrial ecosystems and land cover. A number of researchers began to develop techniques to employ the spectral information from Landsat to measure green vegetation status, and phenology, as well as interannual variation in these parameters. These studies then led researchers to the development of vegetation measures that provide an index of condition and, in part, describe absorption of sunlight, photosynthetic capacity, and evaporation rates. With this research, the science community began to understand that space-based Earth imaging can and does provide information on the spatial and temporal patterns associated with land processes. During this period of capability demonstration, researchers noted that the possibility of developing fully integrated land–ocean–atmosphere monitoring and modeling capabilities were essentially realized.

In March 1984, Landsat 5 was launched and in July of that year, the US Congress provided the legislative authority to transfer the Landsat program to the private sector. Thus began the nearly decade long period of 'commercialization' of the US civil land remote sensing program. Commercialization (and the subsequent price increases for Landsat data) caused a shift in scientific research emphasis. Researchers began to move away from Landsat imagery and began to design experiments using NOAA polar orbiting meteorological satellites and their Advanced Very High Resolution Radiometer sensor system as a primary data source for scientific research. This shift was the result of increased costs, greater restrictions on sharing, and more limited availability of Landsat data to the basic and applied land remote sensing communities.

The US Government would not regain operational control of the Landsat program until the late 1990s. Although the law changed in 1992, government control of any orbital assets did not occur until Landsat 7 was launched in April 1999. The commercial pricing and data-sharing restrictions prior to this transition back to government pricing had restricted research and applications because of high data costs. Not until the twenty-first century did the Landsat program again come under the control of an operational land-oriented federal agency, the United States Geological Survey (USGS).

Despite these difficulties, research using Landsat data during this time (1984–92) included work in many disciplines and application areas. Organizations important in formulating the types of research conducted at this time include the Intergovernmental Panel on Climate Change, the International Council of Scientific Unions, the International Geosphere Biosphere Program, and the Human Dimensions of Global Change project. Particularly significant was research that validated the use of multitemporal Landsat and other data to monitor and assess tropical deforestation and changes occurring in every area of the world.

Other countries entered the space imaging arena with the launch of the French Système Probatoire de la Observation de la Terre (SPOT) satellite in 1986 and the Indian Remote Sensing Satellite in 1988. In 1990, the French launched SPOT 2; a year later the European Radar Satellite (ERS-1) was launched, aimed primarily at oceanographic applications, followed shortly by the Russian radar satellite Almaz; 1992 saw the launch of the first Japanese Earth Resources Satellite. In 1995, ERS-2 was launched and Canada launched Radarsat, with a primary objective of aiding navigation of shipping in the far north. In March 2002, Environmental Satellite (Envisat) was launched by the European Space Agency (ESA) with a suite of sensors to study atmospheric chemistry, ozone depletion,

biological oceanography, ocean temperature and color, wind waves, hydrology (humidity, floods), agriculture and arboriculture, and natural hazards interferometry. The mission lasted until May 2012.

The most recent advances at the end of the twentieth century involved the US launch of Landsat 7 with the Enhanced Thematic Mapper (ETM+) system, the Shuttle Interferometeric Synthetic Aperture Radar (IFSAR) mission, Earth Observing System (EOS)-1 (now named Terra) and EOS-2 (now named Aqua) currently in operation having gathered 10+ years of 250-m spatial resolution data. In addition, in March 1998, a consortium of European nations launched SPOT 4 satellite, the first truly global 1-km spatial resolution polar orbiting satellite, followed by SPOT 5 in May 2002. This mission delivers measurements specifically tailored to monitor vegetation and other land surface parameters with a frequency of about once a day. The role of SPOT-VEGETATION has been taken over by ESA's technologically advanced PROBA-V (Probing Vegetation) mission from June after the expiry of the VEGETATION mission. This marks the transition to a new set of sensors to be launched in the next several years. The 1990s also saw the entry of high-resolution commercial satellites to collect panchromatic images with 1-m resolution and multispectral imagery with 4-m resolution. The suite of commercial satellites known as GeoEye delivers data targeted at commercial and government sectors and is used mostly in intelligence and precision agriculture. Available since 2009 is commercial 22-m spatial resolution imagery from Astrium, targeted at natural resources and agricultural applications from Deimos-1 and Disaster Monitoring Constellation satellites. The Landsat-like data with a combined short repeat cycle (~4 days) is now being used by USDA's National Agricultural Statistics Service Information (NASS) to monitor agricultural growing conditions, improve agricultural land cover classification, and update the crop data layer on an annual basis. The Landsat ETM+ data are already proving useful in a variety of studies from fire fuels mapping to deforestation and urban change monitoring. IFSAR data are helping to improve the quality of topographical maps between about 60° N and 60° S of the Equator. Terra and Aqua data provide continental to global-scale land cover change information with a temporal frequency never before available. IKONOS and GeoEye data enable civil researchers to see features from space that could only be seen if aerial photography or if intelligence satellite data were available to the user.

These satellites are adding immeasurably to our ability to measure, map, monitor, and model our Earth system as never before. The launch of the Landsat Data Continuity Mission (LDCM), renamed Landsat 8, in February 2013 extends the almost 40-year Landsat data archive with image sufficiently consistent from legacy Landsat to allow long-term studies of regional and global land cover change. The two instruments onboard LDCM, the Operational Land Imager (OLI) and Thermal Infrared Sensor (TIRS), will acquire coincident images that will be well calibrated, coregistered, and archived together. This significant improvement of Landsat data will allow for the use of well-calibrated vegetation (from OLI) and land surface temperature (from TIRS) for comprehensive studies of land surface phenomena. At medium-to-coarse resolution the Suomi National Polar-orbiting Partnership launched in October 2011 continues NASA's EOS mission and provides striking new insights into many aspects of Earth, including its clouds, oceans, vegetation, ice, and atmosphere. This mission, the operational successor to Terra and Aqua and jointly operated by NOAA and NASA, enhances the continuity missions under the Polar-orbiting Operational Environmental Satellites umbrella in partnership with European Organization for the Exploitation of Meteorological Satellites, which constantly operate two polar-orbiting satellites. These polar missions will be continued under the next-generation Joint Polar Satellite System program between NOAA and NASA.

Unusual among remote sensing missions of the last decade is the Gravity Recovery and Climate Experiment (GRACE) launched on 17 March 2002. The GRACE mission consists of two identical spacecraft that detect changes in Earth's gravity field by monitoring the changes in distance between the two satellites as they orbit earth 220 km apart. This technique provides critical input to many scientific models used in oceanography, hydrology, geology, and related disciplines, and the derived data are now being used in a variety of applications including measuring the changing mass of polar ice caps, measuring changes in water resources on land, understanding sea level change resulting from ocean temperature and water mass changes, understanding the forces that generate Earth's geomagnetic field, and understanding internal Earth forces that move tectonic plates and result in earthquakes and volcanic eruptions. This along with other future missions including ESA's Sentinel mission and NASA's Global Precipitation Measurement will set new standards for mapping and monitoring facets of the land surface and precipitation environments, respectively, from space.

Future Directions

As of 2013, some 20 governments and organizations have launched civilian and commercial high-spatial resolution satellites in an attempt to capture a share of the growing market for remote sensing imagery. All nations are vested in understanding changes in their resource base and many seek to become global leaders in space imaging. Examples include the China–Brazil Earth Resources Satellite program, which has launched satellites since 1999, and the Indian Space Research Organization, which has launched earth resource satellites almost every 3–5 years since 1998. Japan, China, Pakistan, Argentina, South Korea, Thailand, Turkey, Indonesia, and Nigeria have aggressively pursued satellite remote sensing, with systems with spatial resolutions that range from several kilometers to less than a meter. Developments such as these suggest that a number of the long-standing restrictions that the military and intelligence communities placed on satellite remote sensing are being put aside as the technology becomes more accessible, creating greater transparency among nations of the world. With this increasing transparency comes the opportunity for both positive and negative uses of remotely sensed data. On the one hand, it may be easier to detect violations of international agreements, while on the other it may be easier for states to gain tactically important information on other states.

Remotely sensed data have attracted considerable interest among social, economic, and behavioral scientists. This interest stems from the realization that, although remotely sensed data cannot provide all the data/information needed to answer given questions, it may, when combined with other information, allow data to be more reliably interpreted across space and through time. Indeed, an important aspect of remote sensing is its value as a historical record; applications in legal proceedings involving environmental contamination and ownership liability are but one example. Historical data records from remotely sensed measurement are now required and critical for use in assessment of the impacts of a changing climate on natural resources. Other applications include estimating populations, providing famine early warnings and disaster assessments, inventorying industrial capacity, assessing transportation infrastructure, and monitoring environmental laws and treaties.

Still, users interested in questions in the physical and biological sciences have made more use of remotely sensed data than have users in the social, economic, and behavioral sciences. The reasons for this disparity are many and varied. They range from the inability of remote sensing to provide needed data/information to practitioners in the social, economic, and behavioral sciences to unwillingness on the part of users in these areas to take the time to learn the capabilities and limitations of the information that can be extracted from remotely sensed data. For some applications, the spatial and temporal scales of data acquisition are not appropriate; for others, the models to translate the data collected into meaningful information specific to a given need are yet to be developed. However, changes such as the emergence of distributed data centers, the growth of global Internet networks, and widespread cell phone technology are prompting the use of remotely sensed derived data and maps by all segments of society. Although, remote sensing cannot see what is in the human mind, it can document actions that people have taken in response to some (e.g., environmental) stimuli. For example, remote sensing cannot predict what crop a farmer will plant in a given year, but it can, given appropriate dates of image acquisition and timely interpretation, tell us what has been planted before a crop is harvested. Indeed, given adequate ancillary data and models, satellite imagery can indicate how good the farmer's harvest may be.

As the ability to collect data at higher spatial, spectral, and temporal resolutions increases, so too does the ability to derive useful information from remote sensing data. Remote sensing will never replace other, more traditional methods of data collection, such as census and survey instruments. Yet it is a proven, powerful method of collecting data, which, when properly interpreted and evaluated, can provide a wide variety of useful information. This information, when taken alone or when augmented by other data collected by more traditional means, can create useful data sets for social, economic, and behavioral scientists especially when analyzed together in GIS. The threats posed by climate change and the recognition that these threats are common to all nations have stimulated cooperation among nations in remote sensing missions, research, operations, and applications.

Organizations That Provide Remotely Sensed Data

- Astrium
- ESA
- US NASA
- USGS
- SPOT Image
- GlobeXplorer
- USDA
- US NOAA
- Space Imaging
- DigitalGlobe
- Vision on Technology

Renaissance

Bernd Roeck, University of Zurich, Zurich, Switzerland

Abstract

The present article discusses the uniqueness and exceptionality of the European Renaissance and the multitude of its implications for the emergence of the Modern World. Notwithstanding developments elsewhere, it was only in (Western) Europe where the richness of antiquity was harnessed fully and paved the way for revolutionary breakthroughs in discourse, science, and industry.

In this article the concept of Renaissance will be developed in the sense of a history of ideas, by pointing especially to Jacob Burckhardt's groundbreaking concept of the genesis of the individual, on the philosophy of Nietzsche and the racism of Gobineau, together with Walter Paters aestheticism. In this context, the social interrelations between the functions of the bourgeois Renaissancism (*bildungsbürgerlicher Renaissancismus*) against the background of the growing industrialized mass society will be looked at. This article follows the history of research: i.e., the revisions of Aby Warburg and the 'revolution of the medievalists' (Ferguson). The article then focuses on single aspects of historical research, such as the network of patronage, but more generally on the interrelations between historical fundamental processes. The description of the modern analysis of the Renaissance starts with the discussion of Hans Baron's 'civic humanism'. Additionally, new concepts are discussed. Still central is, in the author's view, the old debate about the genesis of a modern subjectivism and the genesis of the Renaissance in general. The article ends with 'Manierism' and the 'manieristic Renaissance'.

Two nineteenth-century historians were instrumental in giving the term 'Renaissance' the content that it retains to this day. In his 1855 *Histoire de France*, Jules Michelet (1798–1874) chose the word for the period of the *découverte de l'homme et du monde*, the sixteenth century. But the Swiss Jacob Burckhardt (1818–97) was even more important. His famous book *Die Cultur der Renaissance in Italien. Ein Versuch* (1860) became a milestone of research. Burckhardt sketched a monumental fresco that located the origin of modernity in fifteenth-century Italy – in conscious distinction from Hegel's philosophy of history, which posited that the German Reformation marked the beginning of the Modern Age. Burckhardt referred to the conditions in the Italian ministates as 'works of art', in which he saw the preconditions for the 'emergence of the individual' as the most important and far-reaching development of the Modern Age. He presented the Renaissance, with the many-faceted Humanistic movement as its intellectual substrate, as a period that forced the pace of modernization and secularization and as the beginning of the Modern World in which he himself lived and whose negative sides he analyzed perhaps more acutely than any other thinker of his time.

The Development of the Concept of the Renaissance

Renaissance

Burckhardt's thought-provoking image of the epoch exerted substantial influence, not only on the study of history, but also on literature and philosophy, in particular on Nietzsche's thinking. It remains the more or less explicit background of discussions of the term 'Renaissance', though it soon roused dissension. For example, in the book *Franz von Assisi und die Anfänge der Renaissance in Italien* (1885), Henry Thode (1857–1920) attempted a romantic reinterpretation, placing the *poverello* and the religious movement he inspired at the beginning of the epoch. Thode and his followers saw the Renaissance more as a reform movement on a medieval-clerical foundation, eliminating its character as an epoch of its own. Thode rejected the idea that classicism and rationality fundamentally constituted the Renaissance and divided it from the Middle Ages. He posited an individualism of piety and sensitivity to beauty, in contrast to Burckhardt's subjects becoming aware of themselves.

But the prospect of another, religious side of the Renaissance had already existed before Thode and did not completely contradict Burckhardt's view. In his influential essay collection *The Renaissance* (1873), Walter Pater (1839–94), an admirer of Ruskin presented several artists and thinkers he considered representative of the Renaissance. The essay on Botticelli became essential to the incomparable cult of this painter, which thrived throughout Victorian society, and not solely among the Pre-Raphaelites. Botticelli's art seemed to correspond to a 'metaphysical need' in the modern, industrialized world of Victorian England.

The inventions of the historians and literary writers stimulated broad segments of the educated bourgeois class. Florence became the preferred destination for an international cultural tourism. People built in the Renaissance style, surrounded themselves with splendid interiors in the style of the fifteenth and sixteenth centuries, and purchased original works of art. Especially in the second half of the nineteenth century, collections of important Renaissance art were amassed from Boston to Berlin. The 'Renaissance' was not only a focus of scholarly interest, but also part of a lifestyle.

Around 1900, the international Renaissancism reached a zenith. Burckhardt's classic was reprinted again and again, and

novels like Heinrich Mann's 'Göttinnen' depicted the sixteenth century as a foil for the contemporary 'decadent' *fin de siècle*. The closing nineteenth century saw itself not only in a strange spiritual kinship with the Renaissance: the fiction of a 'lascivious', 'unscrupulous' epoch paradoxically appeared to offer counterimages to the usual bourgeois existence, taking shape in princes of commerce, patrons, *condottieri*, and courtesans.

At this time, the term 'Renaissance' was loaded with a plethora of sometimes contradictory meanings, triggering associations of 'gold and purple', as Johan Huizinga said. The patronage of the Medici, the magnificence of the papal court, and the art of the Renaissance with its heroes Leonardo, Raphael, and Michelangelo provided new cult objects for religious worship in a disenchanted world. At the same time, the word recalled the art of power and *Realpolitik*, as Machiavelli had analyzed in his trailblazing work. Racist ideas of a victory of hard men and cunning women over decline and enfeeblement were inherent in this image of the epoch. A widely read literature in the succession of Carlyle, Count Gobineau, Nietzsche, and others popularized the cliché of the 'blond beast', the amoral 'Renaissance man' up to mischief.

The myth of the Renaissance thus offered models for Caesarism and imperialism. It was no coincidence that a nationally oriented writing of history took up Italy's *Signorie* and identified them with the precursors of the modern military and power-wielding state. But the iridescent construct of the 'Renaissance' also offered fragments for a historical foundation of modern civic societies. As early as the beginning of the nineteenth century, the Swiss Sismonde de Sismondi had described the Italian city republics in this way, and travelers from England and the USA thought they were tracing the ideal roots of their own nations when they came to Florence. It is hardly surprising that the inghlesi were the largest group among the tourists. The Florence of the Medici was long a primarily Anglo-American myth.

Examples of the ideological interpretation of the Renaissance with an unmistakable relationship to current history are also found in the works of Hans Baron, a German Jew who emigrated to the USA. In the essay he published in the middle of World War II, he saw the crisis of Italian 'freedom' caused by the aggression of the Visconti *signoria* in the early Quattrocento as the precondition for the formation of a modern, pluralistic state system on the Italian peninsula. In Baron's view, the high degree of citizen participation in Florentine politics was a precondition for this most important result of the struggle against the tyrants: He saw it as a kind of Italian America winning the upper hand over Visconti/Hitler (Baron, 1955).

The Revolution of the Medievalists

More recent research on the Renaissance has tried to free itself of mythologizing. Insight has been sought into the clientele systems of the clan that enabled Cosimo de' Medici and above all Lorenzo the Magnificent to exercise an authoritarian power behind a republican façade (Wackernagel, 1938; Thomas, 1995), whereby special attention was paid to the patrons commissioning the art (Esch and Frommel, 1995). But art history tended to go its own way. Wölfflin and others separated Renaissance art from the cultural history context and treated it primarily as a problem of style, and thus of aesthetics.

The conception of the art historian Aby Warburg (1866–1929) remained fragmentary and accessible only in a very few essays. It aimed once again at the great synthesis and still provides impetus for new research. He located the epoch in a long-term process of civilization that experienced its climax in the Apollonian beauty of the art of the High Renaissance. In the triumph of the Olympic gods, Warburg saw an important step toward overcoming 'oriental', 'medieval' irrationality. He was interested in the difficult breakthrough to the Enlightenment, humanity, and reason in the history of the West. Warburg saw works of art as documents of the states of the human psyche, and he believed that, through subtle analysis, he could uncover the *Zeitgeist* preserved in them. Warburg's works addressed aspects previously not or only marginally considered. The role of the patron became a theme, along with what Michael Baxandall (1972) calls 'troc': the market of intellectual and material goods where what we call 'Renaissance art' took shape. Warburg sought to illuminate the dark side of the epoch – its interest in divination, astrology, and magic, to which Burckhardt had devoted only a few passages. Equally important was that he conceived the emergence of Renaissance culture as a transfer process and thus examined not only the Orient, but also the culture of the North – the courts of Burgundy, France, and the Netherlands. This underscored what is now the general possession of research: the cultural physiognomy of the Renaissance as an amalgamation of varying influences. Italy remained important, but it was placed in the context of a network cast across the continent (Porter and Teich, 1992).

This geographical expansion, the focus on the 'occult Renaissance', and above all his constant question of the beginnings led Warburg to avoid drawing the boundary between the 'Renaissance' and the 'Middle Ages' too sharply. Although his works had no discernible importance for it, he prepared the ground for what Wallace K. Ferguson has termed a 'revolt of the medievalists' (Ferguson, 1948). This debate, characteristic of the 1920s, adopted aspects of the image of the Renaissance as sketched by Thode, Sabatier, and other researchers. It pointed out, for example, that the tradition of antiquity was never completely buried and recalled that various 'renaissances' were palpable between the ninth and thirteenth centuries, in which ancient forms clearly stand out as elements shaping culture. Some researchers, including Etienne Gilson and Johann Nordström saw the Renaissance as a mere continuation of currents existing in the twelfth century. In this famous book *The Waning of the Middle Ages* (1919), the Dutch writer Johan Huizinga drew an image of the fifteenth century diametrically opposed to Burckhardt's conception. Contemplating the courtly world of Burgundy, France, and the Netherlands, he depicted the epoch as a flowering 'autumn' of burgeoning color, rather than as the spring of a new age.

A Movement of the Happy Few: The Sociohistorical Dimension

Discussion thus ensued on the boundaries of epochs; it was the hour of the deperiodizers, who made the Renaissance their preferred target. George M. Trevelyan went as far as to locate the turn from the Middle Ages to the Modern Age in the epoch of the Industrial Revolution, the eighteenth century; and for other

researchers as well (like Delio Cantimori), the Renaissance of the fourteenth and sixteenth centuries lost its meaning as a significant turning point. A more differentiated sociohistorical research underscored that Renaissance societies were more 'medieval' than widely conceived. Additionally, this culture had been borne by a tiny minority – one of the reasons Ernst H. Gombrich no longer speaks of the Renaissance as an epoch, but as a movement.

It is indeed indisputable that epochs named for styles can describe little more than the cultural stances of an often compoundly interwoven elite. Social history has provided glimpses of the world of the majority of the 'Renaissance people'; these reveal little 'Renaissance' quality (e.g., Herlihy and Klapisch-Zuber, 1978; Davis, 1982; Squatriti and Merideth, 1999). Recently, the theme of gender has also been considered more intensely (see King, 1991, with comprehensive bibliography); here, research focuses not only on the 'Renaissance women', the princesses and courtesans who populate the mythological scenario, but also on other women who lived at the time – witches and saints, nuns, artists, authors, and women in working life in general (Ferguson, 1986).

'Modern Individualism' and the Concept of the Renaissance Today

Art Historical Findings

Despite the still current discussion of the term 'Renaissance', the concept has prevailed as the name of a cultural epoch (cf, e.g., Burke, 1972; Delumeau, 1967; Hale, 1993). What arguments can be adduced for or against the concept of the Renaissance? The most conspicuous are the findings of art history, and they were what gave the essential impetus to construe the epoch in the first place. Thus, it is beyond doubt that the painting of Giotto and Massaccio and the sculpture of the Pisani in the fourteenth and fifteenth centuries marked a fundamental transformation. What was decidedly new in painting was that dependence on the Byzantine model was overcome. Here, Flemish influences played a major role, and the Renaissance in general increasingly appears as a complex amalgamation of transfer processes embracing Europe, the Middle East, and finally the New World. The early Quattrocento brought the introduction of a central perspective formulated with geometric precision, a Florentine invention. The goal was to create the illusion of 'real' living beings, objects, and spaces.

One of the most important arguments for Burckhardt's old 'individualism hypothesis' is still that not only did artists' signatures appear even more frequently, but also that, in the fifteenth century, initially in the Netherlands and Italy, portraits were painted that appear closer to nature than anything since classical antiquity. Since the Trecento, sculpture once again clearly approached antiquity's conceptions of the body, and, increasingly frequently, portrait busts clearly strove to convey the individuality of the person portrayed. While it cannot be claimed that the 'modern individual' was invented in the fifteenth century, if we also adduce literary testimony in the broadest sense, for example Ghiberti's *Autobiography* and Giovanni Ruccelai's unique *Zibaldone*, we do note that reflection on the self-gained decisively in importance (Davis, 1986, is highly differentiating; see also Schulze, 1996; Porter, 1997; Schweikhart, 1998).

In architecture, the building forms of classical antiquity reappeared first and initially exclusively on the Italian peninsula. Only at the beginning of the sixteenth century was anything remotely comparable found north of the Alps, starting with the buildings commissioned by the Fuggers in Augsburg. Regional variant forms emerged rapidly. Their common denominator was a more or less clearly articulated reference to antiquity. With mannerism, the Renaissance flows into a typically European style (cf Section The 'Mannerist' Renaissance).

The Revolution in Discourse and Renaissance Humanism

The art of the Renaissance developed in a complex content with a theoretical discourse that, on the one hand, used texts from antiquity, for example Vitruvius' theory of architecture. This was new and genuinely Italian. In the fifteenth and sixteenth centuries, no other European country produced a theory and critique of art whose quality and differentiation were even remotely comparable. Italy was also the first place with a palpable group of collectors, art agents, and patrons who, for aesthetic considerations, acquired real or putative ancient objects. These inspired an almost romantic veneration and learned discussion and correspondence. One of the earliest representatives of this modern phenomenon of collecting was the Florentine Niccolò Niccoli (1364–1437).

Interest in ancient and contemporary art was part of the humanistic culture that was closely tied to the Renaissance. The term *studia humanitatis* is of ancient origin and refers to education in the broadest sense, the acquisition of knowledge as well as of 'good' ways of living. The fifteenth and sixteenth centuries saw the emergence of the social type of the *humanista*, the scholar concerned with the canon of humanistic studies – grammar, rhetoric, poetics, history, and moral philosophy – with recourse to the authors of classical antiquity. Humanistic scholars and humanistically educated elites became the real bearers of the Renaissance. They gave art, architecture, and literature essential elements of form and content (see, e.g., Wind, 1968; Panofsky, 1962). Modern research sees the first beginnings in upper Italy in the second half of the thirteenth century. But Francesco Petrarca (1304–74) was the first thinker to unite in himself the essential aspects of the humanistic movement. The older idea that the humanists were a group of traveling scholars staging a revolution against scholastic theology and church doctrines is no longer tenable. Social history cannot view the host of humanists as homogeneous, even as early as the fifteenth century. The majority of the humanists of Florence, the 'capital' of the Renaissance, were economically well off (Martines, 1968). Monks, prelates, princes, university scholars, urban jurists, and many others spread the *studia humanitatis* in Europe, and in many places humanism established itself as a national movement with national characteristics.

Humanism, and with it the culture of the Renaissance, were in no way pagan. The vast majority of humanists were firmly based in Christianity, and this did not change with the Reformation (Verdon and Henderson, 1997). Significantly, pictorial subjects remained mostly religious during the Renaissance. In the sixteenth century, however, we note their gradual

dwindling (Burke, 1972), a telling indication that Renaissance humanism contained substantial potential for secularization. The great expansion of the spectrum of questions discussed and written about in the fifteenth and sixteenth centuries was of long-term importance. Theology and religion still dominated, but texts on every possible aspect of life increasingly moved to the foreground; finally, and again with recourse to ancient thinkers, a new theory of politics developed (Pocock, 1975). This 'differentiation of discourse' did not depend on the Gutenberg Revolution, but began much earlier. In a certain way, the invention of the letterpress with movable type can be viewed as a response to a market ravenous for written material.

The Research Problem of the Genesis of the Renaissance

A question equally fascinating and controversial is why the beginnings of humanism and the Renaissance lay in Italy and what led to the formation of these movements. As Burckhardt had already underscored, there was the multiplicity of *signoria* and city republics, whose political rivalry sought artistic representation. Ancient monuments, statues, and other relics also provided models. Italy and Flanders, the regions in which the new culture developed, were probably the richest in Europe at the time, so here is where the economic prerequisites for extensive patronage were given. But the connection between art and economy should not be absolutized. There is no necessary parallel between the unfolding of Renaissance culture and a general economic upswing; Roberto S. Lopez (1963) even attempts to interpret the Renaissance as an attempt to compensate for crisis-like developments. The financial position of the patrons was decisive (see, e.g., Roover, 1963). The *condottieri* wars in fifteenth-century Italy resulted not merely in a destruction of resources, but also in processes of redistribution from the great centers to small seats of courts like Urbino and Bergamo, where successful military commanders spent astronomic sums on books and in patronizing the arts. It is difficult to estimate the significance of the dynamics of economic shrinkage triggered by plague epidemics and failed harvests in the first half of the fourteenth century. Along with the resulting acceleration of urbanization, the consolidation of capital in the hands of the survivors contributed to the financing of early Renaissance art – in part as an 'investment in saving one's soul', which must have suggested itself and seemed necessary against the backdrop of the crisis of church hierarchy and the experiences of the plague era. The Renaissance, humanism, and the Reformation thus appear as varying answers to one and the same problem, namely the determination of the human position in a fundamentally changed world. The writings of Giannozzo Manetti and Pico della Mirandola, the political theories of Machiavelli, the primary Reformation writings of Luther and the invention of the realistic portrait and of central perspectives thus all had the same preconditions.

The 'Mannerist' Renaissance

The question of the end of the Renaissance is no less complex and controversial than that of its beginnings. Art history sees indications of a metamorphosis to the 'Mannerist Renaissance' or to mannerism as early as the second decade of the sixteenth century (Shearman, 1967; Arasse and Tönnesmann, 1997). Literary history usually locates the end of the epoch around 1600. And music history, too, has its difficulties with the question of the definition and temporal boundaries of mannerism (important but controversial, see Maniates, 1979). National differences in particular must be differentiated. Setting the boundaries of the epoch is also made difficult by the fact such important intellectual currents constitutive of the Renaissance as humanism and such aesthetic ideals as the orientation toward the standards of Greek classicism lived on after 1600 and experienced their own renaissances.

There has been no lack of attempts to set the stylistic transformation of the sixteenth century in direct relationship to political and societal changes (the best known is Arnold Hauser, 1979). Structural changes at least in the art market and thus in the relationships between artists and patrons probably played an important role. Europe's princes, the rulers of the rising early modern states, moved increasingly into the foreground as patrons. They used the arts to buttress their legitimacy and to display their grandeur: now, in the sixteenth century, the art of the power availed itself of the power of art more than hardly ever before. Political competition also manifested itself as competition among patrons of the arts. The artists' virtuosity, or *maniera*, had to prove itself in this complicated field.

Over the past decades historiography has increasingly focused on the European Renaissance of the fifteenth and sixteenth centuries in a broad chronological and intercultural comparison. On the one hand, the main interest revolved around its antecedents in the Middle Ages and antiquity; among these efforts were, for instance, Erwin Panofsky's argument of the medieval 'revival' known as the Carolingian Renaissance or the various references to antiquity, usually summed up and discussed under the terms 'Proto-Humanism' or 'Proto-Renaissance' (Panofsky, 1960; Masse, 2010). The wide variety of cultural physiognomies associated with the Italian 'Renaissances' and its many centers has been systematically elaborated on recently (Crouzet-Pavan, 2007), focusing on topics as diverse as the importance of tradition, religiosity, fear of suffering in the afterlife, and the new idea of man. On the other hand, the search for 'Renaissances' in other civilizations continues. For instance, Peter Burke ended his study on the Renaissance with a comparative perspective on the Netherlands and Japan (Burke, 1972). Consequently, these approaches lead to the questioning of the prerequisites of distinct cultural epochs, the uniqueness of the European Renaissance (Goody, 2010; Huff, 2011), their implications for the Scientific Revolution of the Modern Age (Cohen, 2010), and their role in the emergence of the Industrial Revolution. In this context the comparison with China under the Song Dynasty (approximately tenth to thirteenth centuries) promises valuable insights; during its rule, the Middle Kingdom achieved outstanding accomplishments well in excess of contemporaneous developments in Latin Europe. Similarly of importance are questions on the origins and consequences of the widening gap between Latin Europe and the Muslim world, especially after the end of the Fatimid Caliphate (Saliba, 2007). A combination of the following factors may have contributed

to the path taken by the Latin Europe: the multitude of states in Europe and the multiple possibilities of patronage for both artists and scholars they offered; the existence of distinctively separate legal entities such as universities, relatively autonomous urban communes, and their creative middle strata; above all, however, Latin Europe profited from the containment of ecclesiastical power. The basis for these developments was the existence of the rich legacy of Hellenistic Greece. Only in Latin Europe with its widening possibilities of (secular) discourse were these riches of the past harnessed and developed further; the topography of innovation mirrors these facts (Murray, 2003). Other important prerequisites of the Scientific Revolutions included the existence of appropriate means of communication, exemplified by the printing press and the more liberal approaches to illustrating (e.g., the human body) practiced in the Renaissance West. The European Renaissance was quintessential for the emergence of the Modern Age and has especially with respect to the pluralistic effects of discourse and innovation, no parallel in human history.

Repartnering and Stepchildren

Frances K Goldscheider, Brown University, Providence, RI, USA

This article is reproduced from the previous edition, volume 19, pp. 13160–13164, © 2001, Elsevier Ltd., with an updated Bibliography section supplied by the Editor.

Abstract

This article examines three issues. These include (a) the role of children in the likelihood their parents repartner (considering different effects for men and women); (b) the role of such children on the fertility of the unions formed, and (c) the effect of stepchildren on union dissolution.

Introduction

Sexual unions create children and hence, parenthood. Union dissolution creates single parents and absent parents. When these parents enter a new partnership, they may have a new kind of children – stepchildren – children who are not the joint concern of the couple at the start of the union, as at least one member enters the union as a step-parent. This asymmetry in parenthood is likely to shape the partner dynamics that lead to union formation and hence to affect the calculations of those with children (whether coresident or not) and any partners who might join them in a new union. This asymmetry affects their lives as a couple, particularly whether they have additional, joint children, and also affects whether their union survives. This article on children and new partnerships examines three issues: (a) the role of children in the likelihood that their parents repartner (considering different effects for men and women); (b) the role of such children on the fertility of the unions formed; and (c) the effect of stepchildren on union dissolution.

Background

The rapid rise in divorce in most industrialized countries together with the rise in cohabiting unions, which tend to be more unstable than marriages, is creating a new demographic situation for men and women. A union disruption places them in the partner market again, which is particularly challenging for those who are the parents of young children. Although historically, high mortality often left young parents widowed, divorce creates twice as many new prospective partners. Further, whatever wisdom had accumulated for those facing this challenge, has likely been lost. The divorce revolution that began in the 1960s and 1970s in the industrialized countries in the west followed a half century or more of rapidly declining mortality, which sharply reduced widowhood for both sexes and concentrated it at ages when children are older, or even adults. In addition, the early years of the increase in divorce rates disproportionately involved couples without children far more than has been the case in the 1980s and 1990s (Andersson, 1997). Hence, the effect of existing children on new partnerships is not well understood, either in the community of scholars of the demography of the family or in the communities experiencing the new situation. Little is known about how children affect their parents' repartnering, and not much more is known about those partnerships as they develop over time in terms of their fertility and stability. The research community has been further hampered by a lack of appropriate data to study these issues.

The numbers involved are substantial. In the United States, it is estimated that 40–50% of all marriages dissolve and a substantial minority of all children spend some time in a single-parent family (Bumpass and Raley, 1995). Half of both previously married cohabiting couples and remarried couples have children in the household and many of the rest have children living elsewhere (Bernhardt and Goldscheider, 2001). Although such rates are higher in the US than in other industrialized countries, they are rising rapidly outside the US (*see* Second Demographic Transition), while US levels appear to have reached a plateau in the last two decades of the twentieth century. At whatever level, these trends mean that a substantial proportion of adults are at risk of entering a new partnership, and many of those who do will have children, either living with them or dependent upon them financially. Those considering forming a union have to take their potential partner's children into account.

A critical question might be whether the presence of children increases the likelihood that the unions formed are cohabiting ones. There is some evidence that this is, in fact, the case. Although the rise in cohabitation has not fully offset the decline in proportions married among the never married, the offset is total among the formerly married, suggesting that remarriage is being replaced by cohabitation (e.g., *see* Second Demographic Transition). However, most research, and most of the data on which research could be based, has made it difficult to study cohabiting partnerships that involve children. Research on 'single-parent' families has frequently studied only 'unmarried' parents. The most common control for resources in families was 'family income,' which typically excluded the income of 'non-family' members, i.e., cohabiting partners. New surveys, such as the Family and Fertility Surveys (FFS), should overcome these difficulties.

Repartnering of Parents

Nearly all research on repartnering when pre-existing children are involved has considered only women with coresident

children, focusing almost entirely on remarriage and on the US. These studies have typically found that the presence and sometimes the number of children reduce women's likelihood of marrying, with effects often depending on the ages of the children and of the mother. One of the few studies that considers cohabitation suggests that children reduce the partners' commitment to the union, decreasing the risk of getting married but increasing the risk of cohabiting (Bennett et al., 1995).

There is much less evidence on how children affect *men's* likelihood of union formation. A major problem for men is distinguishing between coresidential and non-co-residential children, a distinction that has been less important for women. One study examined widowers, where presumably fewer of the children lived with other relatives (Smith et al., 1991). That analysis showed that having dependent children reduces middle-aged (<60) men's likelihood of remarriage after widowhood, although the reduction was much less than is the case for women with children. However, more recent research on both the US and Sweden, which has included divorced and never-married men with coresident children, as well as widowed men, has found that such men enter partnerships significantly *more* quickly than men without children (Goldscheider and Sassler, 2000; Bernhardt and Goldscheider, 1999). This suggests that the effects of coresidential children on union formation are quite different for men than for women.

There is even less research on how non-coresidential children affect union formation, although this is a particularly important issue for men (and the women who consider entering unions with them). The studies mentioned above also examined this issue, and found that in both the US and Sweden, men with non-coresident children are significantly *more* likely than otherwise comparable men with no coresident children to enter a union than to remain outside a partnership. In Sweden, such men are also more likely to enter a union with either a woman who has co-resident children or one who does not than to remain unpartnered; in the US this effect does not appear for union entry for women without children. The few women who have non-coresident children are also more likely to enter a union than to remain outside a partnership. In this case, however, at least in Sweden, they are much more likely to choose a partner with no coresident children, although this effect may reflect the small numbers of nonpartnered men who live with their children.

Perhaps a more important question, however, is the broader one: what factors affect entry into a union with a partner who has children? Research on the US and Sweden shows that two family-related factors distinguish men by whether the partnerships they enter into include children: their parents' marital history and their own marital history (Bernhardt and Goldscheider, 1999; Goldscheider and Sassler, 2000). Men who experienced a nontraditional family structure in childhood are significantly more likely to form a marriage that converts them into stepfathers than one that does not, and the same general difference appears for cohabitation.

US men who have been previously married resemble those who are already parents, in being very likely to enter a union (Goldscheider and Sassler, 2000). If they marry, there appears to be no difference in the likelihood that their partner has children or not. If the new union is a cohabiting one, however, they are more likely to enter one with children. In fact, divorced men are more likely either to marry or cohabit with children than to remain unpartnered; and they are significantly less likely to cohabit without children than to remain outside a partnership. Similar results were obtained for Sweden (Bernhardt and Goldscheider, 1999).

Men who enter unions with children are not simply different in terms of their family histories, however; the evidence for both Sweden and the US suggests that they are also drawn from among the less educated, but the studies do not show why. In Sweden, those with a post-gymnasium education are the most likely to enter a union with a partner without children but the least likely to enter a union where the new partner has children (Bernhardt and Goldscheider, 1999). This pattern is the same for US men; college graduates are more likely to enter a union than to remain outside a partnership if the woman does not have children. They are more likely, however, to remain outside a partnership than to enter a union with a women who has children (Goldscheider and Sassler, 2000).

These results suggest that there are important differences in the likelihood of repartnering for those with and without children, with patterns that differ between men and women. Children, whether co-resident or not, increase repartnering for men, but only non-coresident children do so for women; for them coresident children have the opposite effect. This suggests that surveys need to go beyond providing information in their partnership histories about whether partners brought children into the union and at least also provide information on whether partners have children living elsewhere. Such children clearly affect union formation; it is likely that they would also affect partnership dynamics (fertility and union stability), though this cannot yet be assessed fully, as we shall see in the next section. It is also likely that other characteristics of the children, such as their sex, might affect their parents' repartnering. No studies to date, however, have assessed whether the gender of the child(ren) matters. This question will take on increased importance later in this article.

More fundamentally, it becomes increasingly important to understand the reasons why children reduce the likelihood of repartnering, which we now see is only the case when they are coresident children and are children of the woman and not the man (unless he is older and widowed). How important is the fact that, although in most industrialized countries stepfathers have few legal rights or responsibilities vis-à-vis their stepchildren, most men realize that the children will be claimants on their incomes, at least while they remain in the household? The effect of having coresident children appears to be less for Swedish women than for women in the US (cf Bernhardt and Goldscheider, 1999; Bennett et al., 1995). It may be that the greater support provided to children of all kinds by the Swedish state offsets some of the perceived liability for prospective stepfathers.

A perhaps equally important problem is ambiguity over the nature of stepfather–stepchildren relationships. Stepfathers are discouraged from assuming parental responsibilities for their stepchildren's lives by the children, their mothers, and by the larger society in most western, industrialized countries. Paternal involvement is an important factor in family dynamics, particularly for union stability, and we will examine this topic below.

A further interesting question is how much of the decline in marriage formation is a result of the increase in potential partners with children? Most studies that have examined whether the quality of the partner market has declined have considered women's decisions and have examined trends in the earnings of unmarried men who would be their potential partners. It might be equally interesting to study men's decisions and examine whether trends in men's marriage likelihood are influenced by the changing composition of potential female partners, as increasing proportions have children living with them.

Fertility of Couples with Children from Previous Relationships

There have been more studies on the effects of children from a previous union on childbearing in a new union than on repartnering. Few, however, distinguish between coresident and non-coresident children, and none have taken into account the selectivity of repartnering when children are already present as revealed in the studies reviewed above. Nevertheless, these studies have assembled an impressive set of results for a wide range of industrialized countries in Europe, as well as in the US.

Not surprisingly, the general finding is that couples in later unions have lower fertility within those unions than do couples in otherwise comparable first unions, which indicates clearly that many individuals have childbearing goals they do not want to exceed. Their previous children are considered in their decisions to continue childbearing. This result has appeared in studies in Germany, Czechoslovakia, the US, France, and Sweden (cf references in Vikat et al., 1999).

How much previous children matter and whether it makes a difference whether they are coresident or not remain open questions. They are much more difficult questions to assess for the moment, as there is rarely information on previous children for both members of a couple, particularly on their non-coresident children. The most complete study is a recent analysis of Swedish data (Vikat et al., 1999), which, although it only had data on non-co-resident children for one member of the couple, produced a number of interesting findings.

First, the study found that the effect of previous children is definitely not total, as couples in Sweden appear to have at least one shared biological child independently of previous childbearing by either partner. The authors interpret this result as indicating that joint children are an important element of a union. Second, the authors were able to rule out some alternative reasons for childbearing in later unions. There was little evidence that the risk of having a first child in a union was higher when one of the partners was childless, suggesting that Swedes do not have a child simply as an indicator of adult status. Further, there was little evidence the couples have a child to produce a sibling for a pre-union child, although couples did appear to avoid having only one shared child. This was interpreted as suggesting that it is full siblings that are considered important by Swedish couples in new unions, not half-siblings. Research on the US indicates that while stepsiblings remain fairly close to each other in adulthood, they are much less close than full siblings (White and Riedmann, 1992), although it is unclear how much this difference reflects their different histories prior to coresidence and how much it reflects problems in their relationships while sharing a home. It was not possible to assess how much fertility in repartnerships is affected by coresident as opposed to non-coresident stepchildren, as full information on the latter was not available.

Fertility in repartnerships is clearly a complex subject, and one that might depend not only on the numbers of children each of the partners has had previously and where they live, but also the genders of those children. Strong gender effects appear in research on stepfamily relationships, and there is evidence that gender of children affects union dissolution (Brooks-Gunn, 1994). No studies to date, however, have assessed this issue, as no research has addressed the selectivity of repartnering.

Stepchildren and Union Dissolution

One of the most widely observed characteristics of second partnerships is that they are less stable than first partnerships. Although many have speculated that this pattern was the result of one or more elements reducing commitment (from religious prohibitions to personal orientations toward divorce), a landmark study found that most of the difference in marital satisfaction and in stability could be attributed to the presence of stepchildren. Previously childless persons who repartnered had very little greater risk of union dissolution than those in first partnerships (White and Booth, 1985). Studies of union dissolution since then have generally included indicators of the presence of non-joint children as well as joint children, and found that whatever protective effect joint children might have does not characterize stepchildren, who increase the risk of separation. Little research has been done, however, on what types of stepchildren contribute more to this effect. Are the ages of the children a factor? Is their sex? Does the involvement of the step-parent and/or of the non-coresident parent matter? An even more important element might be the parenting practices of the new partners. Two studies of paternal involvement that was restricted to first partnerships showed that greater involvement of a father with his children increased the wife's marital satisfaction (Harris and Morgan, 1991) and their children's well-being (Amato, 1994); stepfathers are normally less involved with their stepchildren than are biological fathers (Marsiglio, 1991).

Related to this issue is a startling finding – that couples with daughters are more likely to divorce than couples with sons (Morgan et al., 1988). The key to this result appears to be paternal involvement with children. Men tend to spend more time with their sons than their daughters, both in one-on-one conversation and in terms of participation in *family* activities, sharing more meals, leisure time, and home activities with them (Cooksey and Fondell, 1996). In a sense, stepchildren may be like daughters for many men, children who they wanted less, who they do not relate to as closely, and who they can leave more easily. This may also account for the commonly observed phenomenon that sons often benefit more by their mother's remarriage than daughters (Brooks-Gunn, 1994). Given the increased importance of repartnering in the lives of children and their parents in western, industrialized societies, understanding this phenomenon needs to be a high priority.

This article is a revision of the previous edition article by R.A. Prentky, B.K. Schwartz, volume 23, pp. 15893–15897, © 2001, Elsevier Ltd.

Abstract

This article provides an overview of sex offender legislation, cases, treatment, and research, including juvenile sex offenders and the new challenging area of Internet sex offenders. Laws pertaining to sex offenders have waxed and waned throughout the years. Legislation enacted in response to notable crimes and public response include: the Jacob Wetterling Crimes Against Children and Sexually Violent Offender Registration Program, also known as 'Megan's Law,' the Pam Lynchner Sexual Offenders Tracking and Identification Act, the Adam Walsh Child Protection and Safety Act. Treatment models for sex offenders typically employ a relapse prevention (RP)/cognitive behavior therapy (CBT) model and frequently target impaired intimate relationships, victim empathy, anger management, impulse control, antisocial personality features, lifestyle impulsivity, cognitive distortions, sexual fantasy, and deviant sexual arousal. In addition to RP and CBT, treatment modalities include behavioral modification (covert sensitization), pharmacological interventions, dialectical behavior therapy, restorative justice model, risk-needs-responsivity, and the good lives model. Treatment efficacy along with challenges to treatment and management of sex offenders are discussed.

Designation of a subclass of sex offenders as 'repetitive' derives from sexual psychopath legislation that sought to confine sex offenders for indeterminate periods through civil commitment. In response to horrendous crimes committed by a few sex offenders released from prison, states passed a series of laws providing for the involuntary, civil commitment of individuals identified as 'sexually dangerous persons,' 'sexual psychopaths,' or 'mentally disordered sex offenders.' Thirty states passed such laws. During the 1970s and 1980s these laws were successfully challenged in court and many were repealed. By the mid-1980s, only a half dozen states remained with such laws. In 1990, a sex offender recently released from a prison in Washington state abducted, raped, and castrated a 7-year-old boy. An outraged public demanded a response, and involuntary commitment was resurrected. The legality of the Washington statute, as well as other similar laws, were immediately challenged, and a Kansas statute, identical to Washington's statute, reached the US Supreme Court. In what would become a landmark case, the Supreme Court upheld the constitutionality of the Kansas statute (*Kansas vs Hendricks*, see below).

Sex Offender Legislation

Beginning in the mid-1990s, Congress passed many laws governing the management of sexual offenders, most of which focused on community notification. These laws included: (1) The Wetterling Act, passed in 1994 as part of the Violent Crime Control and Law Enforcement Act (42 U.S.C. 14071); (2) the amended Wetterling Act of 1996, officially called the Jacob Wetterling Crimes Against Children and Sexually Violent Offender Registration Program, also known as 'Megan's Law' (P.L.104–105); (3) The Pam Lynchner Sexual Offender Tracking and Identification Act (42 U.S.C. Cardiac Disease, Coping with) of 1996; (4) The Wetterling Improvements Act of 1997 (P.L. 105–119); and (5) The Adam Walsh Child Protection and Safety Act of 2006 (P.L. No. 109–248, 42 U.S.C. 16901).

The amended Wetterling Act of 1996 ('Megan's Law') encouraged all states to institute a procedure for community notification, and The Adam Walsh Act (AWA) established a comprehensive national registry of sex offenders. Title I of AWA, entitled the Sex Offender Registration and Notification Act provided minimum guidelines for sex offender registration and notification, and specified minimum registration time frames (i.e., 15 years, 25 years, lifetime) based on the convicted sexual offense, without consideration of psychological status or risk level. The Pam Lynchner Sexual Offender Tracking and Identification Act established a national database of sex offenders to assist law enforcement in tracking sex offenders across state lines.

The *Hendricks* Era

The single most influential court decision in the decade of the 1990s was *Kansas vs Hendricks*, U.S., 117 S. Ct. 2072 (1997). The Kansas statute established procedures for civil commitment of persons who, due to a 'mental abnormality' or a 'personality disorder' were likely to engage in 'predatory acts of sexual violence' (*Kan. Stat. Ann. Sec.* 59-29a01 1994; *Kansas vs Hendricks*). Kansas invoked the act for the first time to commit Leroy Hendricks, a 60-year-old man with a long history of taking 'indecent liberties' with children, and who was scheduled for release from prison shortly after the act became law. According to Justice Breyer, in his dissenting opinion, Hendricks had a 'serious mental disorder' (pedophilia) that rendered him dangerous because of a 'specific, serious, and highly unusual inability to control his actions' (Cornwell, 1998: p. 397). In a subsequent landmark case (*Kansas vs Crane*, 534 U.S. 407 (2002)), the US Supreme Court upheld the Kansas Sexually Violent Predator Act. At present, 20 states have statutes patterned after the Kansas statute. All of these statutes include the word *predispose* or *likely* (i.e., the mental abnormality makes the person *likely* to engage in sexually violent behavior or

predisposes the person to engage in sexually violent behavior). Although *Hendricks* affirmed the importance of volitional impairment, the subsequent *Crane* decision clarified that *Hendricks* did not have complete lack of control, only some degree of impaired control. Precisely what constitutes 'lack of control' in general and partial lack of control (*some degree of*) in particular has never been clarified.

The clear implication is that sex offenders, to be eligible for civil commitment, must be incapable of controlling their impulses to act out sexually in unlawful ways. Indeed, in those cases where diagnostic criteria may be inferred, the predominant *behavioral* criterion for the old sexual psychopath statutes and the current sexual predator statutes involves some form of volitional impairment (i.e., an inability to control impulses to engage in acts of sexual aggression). Impaired impulse control is, at least in principle if not in reality, associated with 'repetitive' offenses. Thus, the 'modal' individual committed under these civil commitment statutes is a repetitive or habitual sex offender who has an inability, or an impaired ability, to control his impulses to offend sexually. Although the use of the word 'repetitive' in statutory lexicon tells us relatively little about the individual, clinically or dynamically, it does inform us about risk. Repetitiveness clearly is a risk factor for reoffense. Thus, although all offenders with multiple known sexual crimes may be classified as 'repetitive' and arguably pose a greater risk for reoffense, those same offenders may be highly heterogenous with respect to etiology and clinical/treatment issues. One of the resulting conundrums in designing treatment programs is that many clinical issues that would seem logical targets for treatment (e.g., victim empathy, remorse, denial, and cognitive distortions) are not significantly related to reoffense.

Treatment Models for Sex Offenders: Relapse Prevention

Models for treating these 'repetitive' sex offenders are no different from models used to treat sex offenders not classified as predators or as repetitive. Historically, the dominant model for treating sex offenders has been relapse prevention (RP), a cognitive-behavioral approach that was adapted from an intervention intended for use with alcoholics (Marlatt and Gordon, 1985). The theory guiding its adaptation for sex offenders assumed that sexual offending behavior has identifiable triggers (with cognitive, emotional, and behavioral aspects) that must be identified and dealt with in healthy ways to interrupt the offense cycle (Pithers et al., 1983). The RP model and its many elaborations and revisions has been the subject of numerous articles, chapters, and books over the past three decades (Laws, 1989; Schwartz and Cellini, 1995, 1997; see *Sex Offenders, Clinical Psychology of*). Modifying any unwanted behavior stems from the informed consideration of those factors that are most importantly associated with the emergence and the sustenance of that behavior. From the ample research on addictive disorders, particularly alcoholism, smoking, and obesity, there has emerged a substantial literature on preventing relapse (Brownell et al., 1986). As noted, RP, as a model, was revised and adapted for use with sex offenders (Laws, 1989; Laws et al., 2000). Although sexual aggression derives from a substantially more complex amalgam of factors than most addictive disorders and typically reflects a chronic pattern of maladaptive behaviors, the underlying principles remain similar. That is, before designing strategies for modifying sexually aggressive behavior, those factors that are most importantly related to the behavior (i.e., determinants of relapse) must be identified. Although the factors discussed here are, by no means, inclusive, they do represent the core components of most contemporary treatment programs.

Core Elements of Most Treatment Programs for Sex Offenders

The following core elements occur within a cognitive-behavioral therapy (CBT) framework that may be administered on an individual and/or group format.

Impaired Adult Relationships

Impaired relationships with adults reflect a broad dimension of social competence that is temporally stable and multiply determined. Although social skills training is one of the most frequently included components of treatment for sex offenders, its role in relation to sexual aggression remains unclear. Because there are many facets to social competence, specifying what aspect one is assessing is critical. For instance, although there is reasonable support for the conclusion that rapists have assertiveness problems, differences in other areas of social competence are less evident. Likewise some child molesters, such as 'pedophiles,' have a variety of social and interpersonal inadequacies.

Although the question of the etiologic importance of social competence remains uncertain, the inclusion of techniques to address social skills deficits is still clinically appropriate. In addition to social skills training, the modalities that are most often used to improve relationships with adults include assertiveness training, relaxation training, systematic desensitization, sex education, and self-esteem enhancement.

Lack of Empathy

In all domains of interpersonal violence, a general lack of empathic relatedness for one's victim can be regarded as a powerful disinhibitor. Alternatively, the presence of empathic concern may serve to inhibit aggression. There is a clear clinical rationale for assuming the presence of such deficits and targeting interventions to enhance empathy.

Hildebran and Pithers (1989) described the importance of developing empathy for all victims of sexual abuse as an essential first stage of treatment, followed by the development of empathy for one's own victims. At this point most sex offender treatment programs include a separate component for increasing victim empathy. Indeed, Knopp et al. (1992) found in their survey of treatment programs in North America that 94% included victim empathy training. In addition to the standard exercises and tapes (video and audio) used in victim empathy training, expressive therapy may be used to increase the offender's emotional or affective

response to the distress of the victim. Some programs introduce victim advocates, victim counselors, and occasionally victims to increase further the emotional impact. Moreover, increasing the offender's affective appreciation of his own childhood experiences of victimization can instill a greater awareness of his victim's experience of abuse.

Degree and Nature of Anger

The degree and nature of anger evidenced in the assault has long been assumed to differentiate between offenders who were – and those who were not – willing to use extreme force to gain victim compliance (Prentky and Knight, 1991). Sex offenders differ considerably in the nature and extent of their anger and the ways that anger manifests itself in their crimes. Sex offenders who intend only to force victim compliance are likely to vary widely in the amount of aggression evident in their offenses. When the aggression clearly exceeds what was necessary to force victim compliance, the motivation and manifestation may also vary considerably. In some cases, the anger may be undifferentiated with respect to victims (i.e., the offender may be globally angry and express his anger at any available target), and in other cases the offenders may be focally angry at women (i.e., misogynistic anger) and displace their anger at women in general or on specific groups of women (e.g., prostitutes or the elderly). Similarly, child molesters who intentionally inflict considerable physical injury on their victims may be focally angry at children.

The recognition of the critical importance of anger as a driving force in sexual offenses has resulted in the inclusion of treatment techniques to reduce and contain anger. The most commonly employed of these techniques is an anger management group that uses cognitive-behavioral strategies to increase self-control as well as the timely and appropriate expression of angry feelings. In addition, RP, which also focuses on increasing self-management skills, and stress management can assist the offender to gain control over chronic and situationally induced anger. Finally, early life experiences of victimization can fuel lifelong anger that is periodically triggered by real or imagined provocations. A group that focuses on childhood victimization can help the offender to master these traumatic events.

Cognitive Distortions

Cognitive distortions are 'irrational' ideas, thoughts, and attitudes that serve to: (1) perpetuate denial around sexually aggressive behavior, (2) foster the minimization and trivialization of the impact of sexually aggressive behavior on victims, and (3) justify and sustain further sexually aggressive behavior. Cognitive distortions are presumed to be learned attitudes that are instilled at an early age by caregivers, reinforced by peers during childhood and adolescence, and further strengthened in adulthood by the prevailing social climate.

The social and cultural forces that have been hypothesized to contribute to sexual violence include the permissive responses of a wide variety of social systems and institutions that function to perpetuate rape myths and misogynistic attitudes, the objectification and exploitation of children and women in pornography, and the often similar but more subtle messages conveyed in advertising that support, or at least condone, sexual harassment (Stermac et al., 1990). The importance of cognitions in moderating sexual arousal has been repeatedly demonstrated. Moreover, clinical observations have suggested that many sexual offenders harbor offense-justifying attitudes and that these attitudes are importantly related to the maintenance of the 'sexual assault cycle.' Thus, the modification of irrational attitudes has been a major focus of treatment intervention. Although there are a variety of treatment modalities that may impact these distortions, the most commonly employed technique is cognitive restructuring. For cognitive restructuring to be most effective, it is critical that cognitive and affective components be addressed. That is, it is insufficient merely to confront the 'distorted' nature of the attitudes, to discuss the role that such distortions play for the individual, or to provide accurate information about sexual abuse (all cognitive components). It is equally important to create discomfort by focusing on the victim's response (e.g., fright, pain, humiliation) – the affective component. This latter exercise is also integral to victim empathy training.

In addition to cognitive restructuring, a group that focuses on childhood victimization can also be very helpful. Since the origin of these distorted attitudes is often a primary caregiver who was an influential role model, as well as exposure to peer role models, often in institutional settings, a group that focuses on these early adverse life experiences can help to trace the cognitions to their source, thereby challenging the generality of these attitudes, diminishing their logic or their 'truth.'

Sexual Fantasy and Deviant Sexual Arousal

Sexual fantasy refers to cognitive activity that focuses on thoughts and images having sexual content, and deviant sexual arousal refers to an arousal response that is prompted by thoughts, stimuli (visual or auditory), or behaviors that are defined as unconventional or antisocial by society. Studies investigating the relation of sexual fantasy to sexual aggression have typically employed plethysmography to assess sexual arousal to auditory and visual stimuli that purportedly tap specific sexual preferences. The guiding premise of these studies has been that deviant sexual fantasy is highly correlated with deviant sexual arousal and that both deviant fantasy and deviant arousal patterns are important precursors of deviant sexual behavior (Prentky and Knight, 1991).

The frequent targeting of such fantasies for therapeutic intervention reflects the widely held belief that the modification of deviant sexual fantasies and deviant sexual arousal patterns is critical for the successful treatment of sex offenders. Indeed, the presence of deviant sexual fantasies does appear to increase the likelihood of subsequent deviant sexual behavior. Moreover, the moderate success at increasing nondeviant arousal and behavior by applying techniques aimed solely at modifying arousal to deviant sexual fantasies supports the hypothesis that deviant fantasies not only lead to and maintain deviant sexual behavior but also impede normal sexual adaptation.

Behavioral techniques for modifying sexual arousal patterns are grouped into two categories, those that decrease deviant arousal (e.g., covert sensitization, aversion,

masturbatory satiation) and those that increase appropriate arousal (systematic desensitization, fantasy modification and orgasmic reconditioning). Although numerous behavioral techniques have been reported in the literature, the most widely used method has involved some variant of aversive therapy.

In addition to the repertoire of behavioral interventions, somatic treatment has become increasingly popular as a complement to psychological treatment. These organic or drug treatments consist primarily of antiandrogens (Bradford, 1989) and antidepressants (Kafka, 1991). The antiandrogens (e.g., medroxyprogesterone acetate and cyproterone acetate) reduce sexual drive by reducing the level of testosterone. The antidepressants that are used are primarily the selective serotonin reuptake inhibitors, such as fluoxetine. Although the neuroregulation of sexual drive remains unclear, there is some evidence that enhanced central serotonin neurotransmission inhibits sexual arousal. In addition, there is clinical evidence that uncontrollable sexual urges and compulsive sexual behaviors are associated with dysthymia and major depression.

Antisocial Personality/Lifestyle Impulsivity

In research on sexual offenders, impulsive, antisocial behavior has proven to be a critical risk factor for recidivism (Hall, 1989; Prentky and Knight, 1986). There is increasing evidence even within noncriminal samples (e.g., college students) that the likelihood of engaging in sexually aggressive behavior is greater among those who are more impulsive (Prentky and Knight, 1991).

Clinicians have long recognized the importance of impulsivity for relapse and have introduced self-control and impulsivity management modules into treatment. In addition to groups that focus specifically on impulse control, most treatment programs include components of RP. RP begins by identifying the chain of events and emotions that lead to sexually aggressive behavior. Once this 'assault cycle' is described, two interventions are employed: (1) strategies that help the offender avoid high-risk situations, and (2) strategies that minimize the likelihood that high-risk situations, once encountered, will lead to relapse. This is an 'internal self-management' system (Pithers, 1990) that is designed to interrupt the seemingly inexorable chain of events that lead to an offense. RP is potentially helpful for interrupting patterns of behavior that eventuate in specific outcomes, such as sexual assault, as well as patterns of behavior that are more global, such as impulsive, antisocial behavior.

Beyond CBT: Alternative Treatment Models

There are other treatment models in addition to RP/CBT.

The *restorative justice* model has its roots in indigenous cultures in the United States, Canada, and Australia. The principle of restorative justice is that when someone harms another, it has an effect not only on the victim but also on the extended family, on the community at large, and the person who caused the harm. Unlike all other treatment models, which focus on rehabilitating the offender and managing his risk, restorative justice programs emphasize restoring a sense of well-being not only to those who were harmed, but to the offender, and to all affected members of the community. Through mediation between victims and offenders, reparations, conferencing and negotiation, restorative justice moves justice out of the courtroom and into the community (Rodriguez, 2007). One of the most notable restorative justice programs implemented with sex offenders is RESTORE, designed by Dr Mary Koss (Koss et al., 2003). RESTORE is intended for those who have committed date and acquaintance rape. Restorative justice models have also been used with incest offenders and with juvenile sex offenders.

The *Risk-needs-responsivity* (RNR) model is an offender rehabilitation model developed by Andrews et al. (1990). The RNR model adheres to three important principles: *risk principle* (the most intensive services should target the highest risk offenders), *need principle* (treatment should target criminogenic needs, which are almost entirely dynamic in nature), and *responsivity principle* (treatment should be provided in a way that is most responsive to the offender's abilities). In brief, risk addresses *who* should be treated; need addresses *what* should be treated; responsivity addresses *how* treatment should be provided. As described by Andrews and Bonta (2010), criminogenic needs captures three of the 'big four' risk factors (procriminal attitudes, antisocial personality traits, and procriminal peers). The fourth factor, criminal history, is largely static. The RNR model has been implemented in numerous offender programs in Canada, the United Kingdom, Australia, and New Zealand. RNR has been found to have applicability for female offenders and juvenile offenders as well. RNR has not been widely adopted in the United States and has not been widely used with sex offenders. In one metaanalysis, Hanson et al. (2009) reported that interventions that follow the principles of the RNR model are applied to sex offenders and recidivism rates (sexual and general) are significantly reduced.

The *good lives* model is a 'strength-based' approach that complements CBT with a comprehensive risk-focused intervention strategy for managing sex offenders (Ward et al., 2007). Good lives model emphasizes the development and enhancement of individual strengths while simultaneously recognizing the need to manage risk to reoffend. With at least four recent books highlighting good lives, this model has rapidly achieved widespread recognition (Laws and Ward, 2011; Ward and Maruna, 2007; Yates and Prescott, 2011; Yates et al., 2010). Perhaps a mark of this recognition is competitiveness with RNR. Andrews et al. (2011) questioned whether the good lives model adds anything beyond what RNR already provides, and Ward et al. (2012) responded in kind.

Dialectical behavior therapy (DBT), although not a comprehensive treatment model, has been making slow inroads into sex offender therapy. DBT was originally developed by Dr Marsha Linehan (1993) as a treatment for borderline personality disorder (BPD) and clients presenting with high-risk, self-harming behaviors. Shingler (2004) pointed out that both those diagnosed with BPD and sex offenders exhibit interpersonal, behavioral, emotional, cognitive, and self-dysregulation. The twin rivers corrections center (TRCC) (Monroe, WA) sex offender treatment program is one example

of the adaptation of DBT for use with sex offenders. In the second phase of a two-phase treatment program, the TRCC implemented DBT group skills training in a community setting and found that it was effective in reducing impulsivity and increasing therapeutic alliance in high-risk offenders but not lower-risk offenders (Berzins and Trestman, 2004).

Although treatment programs for juvenile sex offenders have traditionally been modeled on the adult programs, focusing on CBT and RP, a strength-based approach has also been adopted by many juvenile sex offender treatment providers. The Oregon Youth Authority (Dr Keith Kaufman), for example, has designed a variation of this theme, using psychoeducational classes that target competencies, strengths, and healthy adaptations in youth. As noted, restorative justice programs have also been used successfully, though much less frequently, with juveniles.

Challenging Problems in Offender Treatment

The question of treatment effectiveness is a deceptively difficult one to answer due, principally, to the constraints imposed on treating forensic clients in general and sex offenders in particular. The numerous 'intervening' obstacles, which have been elsewhere discussed that may arise when treating sex offenders: (1) in a prison, the highest premium is placed on security, not therapy, and conditions for therapy often are suboptimal (e.g., severe space limitations, limited scheduling options, canceled therapy sessions on a moment's notice, maintaining staff morale in an unsupportive environment); (2) expecting 'clients' to fully disclose and 'come clean' in an environment where it may be dangerous to be known in population as a sex offender, (3) expecting offenders to engage in treatment when confidentiality cannot be assumed or ensured and when the offenders are reluctant 'customers' who have asked to be in therapy, (4) where therapists often are inadequately trained and supervised, (5) where program-related resources are limited and often restricted, and (6) where the 'outcome' variable (survival after release) is determined by a complex legal proceeding, *not* by programmatic considerations (Prentky et al., 2011). Although there are some more encouraging reports, the only randomized clinical trial of sex offender treatment remains that of Dr. Janice Marques (Marques et al., 2005). A prison-based RP program followed those assigned to RP, a volunteer control group and a nonvolunteer control group for an average of eight years at risk. There were no significant differences between the three groups in sexual recidivism. All three groups had roughly a 20% recidivism rate over the follow-up period. Explaining this important outcome study is tricky. It likely speaks more to the difficulties of conducting effective treatment in a penal environment than to the inefficacy of the treatment itself.

Management in the Community

In addition to registration and community notification, residency restriction is another management strategy for offenders living in the community. Residency restrictions often prohibit offenders from living less than 500 feet from where children congregate and therefore severely limit housing options for offenders in the community. In addition to being isolated from the community, additional consequences of residency restriction include limited access to employment and health care, particularly mental health services at a time when they are perhaps the most crucial.

Internet Sex Offenders

The Internet provides a medium through which one can target and groom victims for a hands-on offense, distribute child pornographic images, or find like-minded individuals who share distorted beliefs about child sexuality and child sexual offenses. The combination of *accessibility*, *affordability* and *anonymity*, dubbed the 'Triple-A Engine' by Cooper (1998), make the Internet an attractive, powerful, and efficient vehicle for gratifying sexual interests, including child pornography. Recent advances in smart phone technology allow for practically unlimited Internet access at any time. This has opened the gateway to a new 'type' of child molester: the Internet sex offender who possesses, distributes, trades, and may produce Internet child pornography. Wolak et al. (2005) found that 39% of a sample of child pornography offenders were so called 'dual offenders' (having both child pornography and contact sexual offenses against minors).

Although still in its infancy, the empirical literature suggests that 'Internet-only' offenders (sex offenders who have committed an Internet sexual offense, but not a contact offense) may be a unique subgroup of pedophiles, as they seem to be differentiated from contact offenders. The consistent differentiating factor is antisociality, with contact offenders being significantly more antisocial (Eke et al., 2011; Seto and Eke, 2005; Webb et al., 2007; Lee et al., 2012). Internet sex offenders also appear to be less deviant, less physically aggressive and less impulsive than contact offenders (Tomak et al., 2009). Webb et al. (2007) found that while contact sexual offenders were more likely to 'act out' and break rules, Internet offenders reported more psychological difficulties in adulthood and fewer prior sexual convictions.

The essential question for law enforcement is who, among all those found in possession of Internet child pornography, is at high risk of committing a contact offense against a child, or has already done so and not been caught. Endrass et al. (2009) found that for those individuals without previous convictions for hands-on offenses, accessing Internet child pornography alone is not a risk factor for committing a contact sexual offense against a child. This does not address questions about how Internet child pornography might operate in tandem with or indirectly through other antecedent and risk factors. Seto et al. (2001) recommended that future research look at potential moderators, such as hostility and paraphilic interest.

The Internet can also serve as an environment to promote pedophilic beliefs, bringing together like-minded individuals. For example, Holt et al. (2010) looked at attitudes and beliefs displayed in Web forums for pedophiles. They found that these forums exhibited high levels of cognitive distortions around the following themes: (1) marginalization (i.e., they are victims and not understood); (2) sexuality (i.e., children are sexual beings); (3) law (i.e., information about legal statutes); (4) security (i.e., information about how to evade

the law, how to protect oneself from getting caught). This suggests that the Internet provides a cultural context by which beliefs and ideas about behavior (e.g., sex with children is normal) can be reinforced. A corollary of this is that there may be an interaction between the Internet and other factors (i.e., cognitive distortions).

Conclusion

The primary concerns regarding sex offenders involve community safety, accurate assessment of risk and methods for reducing risk. However, as mentioned, the advent of the Internet brings a host of new concerns to the forefront that must be addressed and are still in nascent stages of investigation. Given the failure of more traditional correctional remedies, such as deterrence and incapacitation, for reducing the level of sexual violence in society, other interventions have been actively sought. One potentially effective intervention for known offenders is treatment. As noted, the verdict as to the efficacy of treatment for sexual offenders is inevitably a complex one that addresses: (1) optimal treatment modalities for specific subtypes of offenders, (2) optimal conditions under which treatment and follow-up should occur, (3) selection (or exclusion) criteria for treatment candidates, and (4) fidelity of the treatment program. At the present time, the most informed and dispassionate conclusion must be that the jury is still out.

The essential point, of course, is the legislative intent of laws that commit sexual offenders for indefinite periods of treatment. If the primary intent of the law is preventive detention, as Pacht (1976) argued 35 years ago, and treatment is merely thrown in so that the law will pass constitutional muster, then it is very unlikely that the law will promote a marked diminution in recidivism among released offenders. The task of effecting behavior change in seriously characterologically disordered individuals is, in itself, considerable. When these individuals have not chosen treatment but are placed in treatment by the court (as is often the case), and when the treatment occurs in the context of a dangerous prison environment where the goal is survival not therapy (as is often the case), then the task becomes immeasurably more difficult. When the treatment provided is suboptimal, the conditions (i.e., prison) are highly problematic, and the therapists are inadequately trained and supervised, the task may well be impossible. Under these onerous conditions it would be an error to draw any conclusions about the presumptive inefficacy of treatment with sex offenders.

This article is a revision of the previous edition article by R. Rosenthal, volume 19, pp. 13164–13167, © 2001, Elsevier Ltd.

Abstract

The ability to successfully replicate previous work has long been identified as the foundation of scientific progress. Exact replication, in which researchers attempt to duplicate a previous study in every respect, is rare compared to approximate replication, which may produce knowledge about the generalizability of a previous finding or the mechanisms that produced it. In the social and behavioral sciences, replication is potentially an important antidote to publication bias caused by researchers' reliance on statistical hypothesis testing. Few replications are published in those fields, however, because their members tend to value novelty and view replication as pedestrian.

The ability of researchers to repeat previous work and obtain the same results has long been viewed as the foundation of scientific progress (Rosenthal, 1991). To foster this, research articles in the empirical sciences usually include a 'methods and materials' or 'data and methods' section that, at least in principle, provides enough information to enable other researchers to replicate the findings those research articles report (this possibility is often termed 'intersubjective testability' or 'reproducibility'). Researchers in fields where inquiry consists of experiments are expected to have replicated their work before publishing it, and experimentalists who publish results that others cannot reproduce usually suffer damage to their professional reputations.

Exact and Approximate Replication

Replications vary in the degree to which they employ exactly the same methods and materials of an earlier study. Exact replications carried out by researchers trying to test the validity of others' work are rare for several reasons. First, they are often costly and difficult to carry out. Second, exact replications that succeed in producing previously reported results are usually not publishable because they contribute little new knowledge. Third, the status of an attempted exact replication that fails to produce previously reported results is often ambiguous because the researcher carrying out the replication may not have succeeded in using exactly the same methods and materials as the original study (Collins, 1985). Thus, attempts at exact replication tend to be limited to cases where the work to be replicated is highly important theoretically or monetarily.

Approximate replications, wherein researchers modify one of more of the procedures or conditions of the original study, are more frequent and are valuable because they may give information about the generalizability of the original results or the mechanisms that produced them (Aronson et al., 1998; Tsang and Kwan, 1999). In some experimental fields, researchers routinely carry out approximate replications of others' work in order to build directly upon it. Routine successful replication of others' work enables a community of scholars to build a scaffold of knowledge made up of interrelated elements produced by different members of the community. A happy coincidence of frequent successful routine replication is that it gives researchers confidence in the validity of their joint enterprise.

Replication in the Social and Behavioral Sciences

Replication is infrequent in fields, including most of the social and behavioral sciences, where researchers do not typically build directly on previously published results. Novel and counterintuitive findings are often much prized in these fields (Guetzkow et al., 2004), so studies that attempt to build on past results, are usually judged to be uninteresting and pedestrian (pejoratively referred to as being only 'normal science'). In addition, many believe that exact replication is impossible in these fields because changing social and cultural conditions beyond the control of researchers may produce differences in the results obtained by studies even if they do use identical methods. The meaning of a failure to replicate previous results is therefore more ambiguous in the social and behavioral sciences than in the natural sciences (Schuman and Presser, 1981).

Many have argued that dearth of replication in the social and behavioral sciences is an important factor limiting the progress of those sciences. This is because researchers in these fields often rely on the results of statistical hypothesis testing as an important determinant of whether their findings are worthy of publication. Specifically, research projects that do not produce results that pass statistical significance tests are not represented in the research literature because editors and reviewers require statistically significant results, and also because authors, anticipating that their work will be rejected if they submit it for publication, decide to not write papers about their results if the results do not pass statistical significance tests. This pattern is referred to by such terms as 'publication bias' and 'the file drawer problem' (Rosenthal, 1991). In contrast, results that do pass statistical tests, even if they are a result of Type-I error, achieve publication. Many have noted that this system raises the possibility that the research literature of the social and behavioral sciences consist disproportionately

of papers that report misleading results (Sterling, 1959), a condition that hinders knowledge accumulation. Consistent with this possibility, surveys of attempted replications that have been carried out in the social and behavioral sciences report high rates of failure (Tsang and Kwan, 1999). A telling exception to this generalization is that studies of the prevalence of replication studies in social and behavioral science journals uniformly report their absence (e.g., Gaston, 1979; Tsang and Kwan, 1999).

In order to increase researchers' motivation to carry out replications and thereby reduce the pernicious effects of publication bias, some argue that scholarly journals in the social and behavioral sciences should reserve a certain proportion of their pages to papers that report the results of replication attempts. Surveys of editors of such journals, however, find that they, like their colleagues, also view replication studies as pedestrian, and therefore unworthy of publication (Madden et al., 1995).

Abstract

The theory of social representations studies the formation and transformation of meanings and activities of complex social phenomena like health and illness, political problems or environmental issues in and through language and communication, history and culture. There are two mutually interdependent meanings of social representations. The first meaning concerns the theory of social representations as an interactional theory of knowledge. It refers to networks of concepts and figurative schemes that are generated in and through tradition, common sense, daily knowledge, and communication; these are shared by particular groups and communities. The main features of this theory are the Ego–Alter–Object, the field, the interdependence of asymmetries and symmetries, ethics, figurative scheme, and cognitive polyphasia. Second, social representations refer to concrete social phenomena and to forms of apprehending and creating social realities in and through communication, experience, social practices, and interventions. Human thinking is characterized by the capacity to make distinctions and understand phenomena as dyadic antinomies or themata. Thematization of dyadic antinomies is linked with anchoring and objectification, through which social representations are formed and transformed.

What Are Social Representations?

'Representation' is one of the most common concepts in psychology. Like many significant concepts that have been part of human thought for a long time, the meaning of 'representation' has radically changed and diversified throughout history. In particular, during the last century or so it has become the basis of numerous theories in cognitive sciences, sociology, and psychology. Adjectives that characterize a representation as mental, collective, or social, identify very different theoretical perspectives. This fact is often ignored or misunderstood, and this leads to substitution of one kind of representation for another one and so to a confusion of their meanings. In order to understand the concept of social representations, we need to clarify how it differs from other kinds of representations.

Mental Representations

The seventeenth-century philosophers René Descartes and John Locke laid down theories of knowledge in which a mental representation played a significant role; these theories of knowledge still steer contemporary conceptions of mental representations. René Descartes' philosophy conceived of the universe as being guided by mechanistic laws of physics, geometry, and mathematics. The same laws of mechanics also pertained to biological organisms and even to language. For Descartes, the self's rational thinking was the only source of certain knowledge. According to John Locke, individuals acquired knowledge by mirroring elements of concrete reality and so constructing more or less correct mental representations. In these ideas of Descartes and Locke, we already find germs of the main characteristics of mental representations as currently studied in cognitive science. The leading cognitive scientists like Chomsky and Fodor, too, presuppose that the mind (indeed the mind/brain) is a mechanism. Terms like the 'mind', 'mental representation', and 'mental computation' among others refer to capacities of the brain to mirror external reality. Operations of the brain are understood in terms of causes and effects or of purposes, governed by rules or by algorithms, for which no historical explanation is required. Today, the study of mental representations is vast and diverse, with many assumptions built into manifold theories, posing different kinds of questions in psychology, philosophy, and cognitive science. Mental representations are conceived as formalizations of rational individuals. In contrast, common sense concepts are conceived as inferior forms cognition; it is believed that with scientific education they will gradually disappear.

Collective Representations

Emile Durkheim's concept of collective representations that he developed in the later part of the nineteenth century is at a crossroad between the static and the mechanistic mental representation and the interactive and dynamic social representation. Like Descartes and Locke, Durkheim was preoccupied with the question as to how one acquires knowledge of the external world. In contrast to Descartes and Locke, he adopted the point of view that the world cannot be understood through representations of single minds, but through collective representations. Collective representations are socially produced phenomena that circulate, and are shared in society, for example, as religious, mythical, or scientific representations. They arise directly from social structures and they constitute social reality just like physical facts constitute physical reality. Durkheim called them social facts; they are external to individuals, who do not contribute toward their formation. Collective representations impose irresistible pressure on individuals who, yielding to their coercion, internalize and perpetuate these social forms of acting, thinking, and feeling. Durkheim conceived the sociology of knowledge as firmly based on the concept of stable collective representations that reproduce themselves through the process of internalizations in single individuals. He insisted that knowledge must be certain and unchanging, otherwise, it would not be knowledge; therefore, collective representations, in order to have the status

of knowledge, they must be relatively stable. Nevertheless, throughout historical development, collective representations slowly change and become more scientific. Like many researchers of his time, Durkheim privileged scientific knowledge over common sense knowledge and thus he perpetuated the idea that common sense thinking is erroneous and trivial.

Social Representations

The theory of social representations studies the formation and transformation of meanings, knowledge, and activities of complex social phenomena in and through language and communication, history and culture. Examples of such phenomena are health and illness (e.g., AIDS, mental illness, or diabetes), political problems (e.g., democracy, totalitarianism, trust and distrust of institutions), environment, and so on. Such phenomena may present danger, threat, as well as hope, for individuals and groups; they invigorate, innovate, and transform society; they create conflict as well as facilitate conformity. The multifaceted characteristics of such phenomena reveal themselves in and through language and communication of various kinds, e.g., in the media, the public discourse, or interpersonal dialogues.

Serge Moscovici proposed and developed the theory of social representations, both conceptually and empirically, in 'La Psychanalyse: Son Image et Son Public' (Moscovici, 1961/1976; English edition in 2008). This classic explored, in a specific sociopolitical culture in the late 1950s in France, transformations of professional and scientific knowledge of psychoanalysis into everyday thinking and discourses of various social groups and the mass media reporting. It would be wrong to assume that transformation of professional and scientific knowledge into everyday thinking is achieved by developing simplified lay theories. Instead, it is accomplished by, and enriched through, diverse means of communication and images, arguments based on trust and distrust of others, collective memories, conscious and unconscious beliefs, myths and metaphors, fears and hopes. Moscovici's work was driven by questioning the prevalent view that ordinary people do not think rationally (Moscovici and Marková, 2000). He objected to the view that a social scientist should study rational thought, which, in the future, would replace inferior common sense thinking. In contrast, Moscovici asserts that a social scientist should study the daily thinking of citizens and the ways of their creating social reality using images, beliefs, language, and communication. Among the forms of daily thinking, common sense is a legitimate field of study for social scientists. Although Moscovici has not explicitly specified what constitutes the epistemology of common sense, one can suggest that this epistemology is carried and transmitted in and through social interaction, language, and communication. It draws on daily thinking and imagination, on figurative schemes, innovation, and ethics.

Two Meanings of Social Representations

We can distinguish two fundamental meanings of social representations. First, the theory of social representations is an interactional theory of social knowledge – or interactional epistemology. (The term 'interactional epistemology' fits with the aim of this article to present a general conception of social representations. Elsewhere when I present my own position with respect to social representations, I use the term 'dialogical epistemology'.) As such, it institutes networks of concepts and figurative schemes that are generated in and through tradition, common sense, daily knowledge, and communication; these are shared by particular groups and communities. The theory of social knowledge enables the researcher to define research problems. The second meaning of social representations is related to the study of concrete social phenomena, to their apprehension, creation and change in and through communication, experience, social practices, and interventions.

Social Representations as Interactional Epistemology

As a theory of social knowledge based on interactional epistemology social representations involve a number of specific characteristics, among which the following appear to be the most significant.

Ego–Alter–Object

The relation between the Ego–Alter–Object constitutes the pillar of the epistemology of social representations: knowledge and beliefs (Object) are generated both by the self (Ego) and by others (Alter). Therefore, the minimum unit in the formation of social knowledge and beliefs is a triadic relation, the Ego–Alter–Object (Moscovici, 1972/2000, 1984; Bauer and Gaskell, 1999; Marková, 2003/2005; Jesuino, 2008). In this generalized model, the relation between the Ego and the Alter stands for all kinds of selves and others; however, in concrete and contextualized situations of knowledge production there is always the specific Ego and the specific Alter. For example, the Ego can be a child and the Alter can be his or her parents; moreover, this dyad, i.e., child–parents, could be conceived as an Ego within a specific culture (Alter), and so on. Thus, the formation and maintenance of social representations can be conceived as multifaceted structures of knowledge and beliefs produced by embedded kinds of the Ego–Alter. This epistemology presupposes that there can be no single mind without other minds: they dialogically coconstitute one another. I am using the term 'dialogically' with reference to 'dialogicality'. Dialogicality is the fundamental capacity of the Ego to conceive, create, and communicate about social realities in terms of the Alter. What the human individual has become through the work of the past, and what his or her prospects are for the future, results from dialogicality (Marková, 2003/2005). Such language-based interdependencies make the dyadic relations between the Ego–Alter dynamic, with implicit and explicit meanings affecting their discourses and contributing to transformation of representations. Participants contribute to different dialogical perspectives and create tensions among them. Neutrality can be only artificially imposed but speech is always judgmental, evaluative, and oriented toward creating new meanings.

The Field

In interactional epistemology of social representations, social reality is not generated from behavior of single individuals. Instead, it results from interactive forces binding the Ego and

the Alter. Such interactive forces constitute a field. Within the field the parties exert a mutual influence on one another, and they jointly generate an object, that is, new patterns of knowledge, beliefs, and images. The field involves forces (e.g., attraction, volition to communicate, the interest in a particular subject matter, repulsion, coordinated attention and intentions, and so on) between communicants (the Ego–Alter) with respect to the object of study. This is why triangularity in the theory of social representations is the basic presupposition; it separates this theory from individualistic theories of knowledge.

Within the epistemological triad of Ego–Alter–Object, relations between these components can take on different forms and commitments. For example, if the individual searches for knowledge of an Object, he or she might be more strongly committed to that Object than to the Alter. In this case, the individual would examine dispassionately the object of knowledge, even ignoring the general consensus with respect to the accepted knowledge.

Another kind of relation within the triangularity of the Ego–Alter–Object could be based on a strong relation between the Ego and Alter, whereas the relation between the Ego and the Object could be treated as secondary. In this case, knowledge/beliefs could range from irresistible to those that would function as constraints – be it compliance, conformity, or obeisance. Irresistible beliefs created by interdependence between the Ego–Alter can hardly be changed by evidence or by persuasion to their contrary. They can lead to self-sacrifice and other-sacrifice of individuals and groups, rather than to their change. Such strong beliefs within a group, e.g., religious or political, are often based on trust and trustworthiness of the other; convictions, rituals or ideas can take possession of us and they take control or our reasoning (Moscovici, 1993: p. 50).

The presupposition of triangularity, of course, will lead to the inclusion of other components in the process of generating social knowledge, e.g., time (Bauer and Gaskell, 1999), location, cultural resources (Valsiner, 2003; Chryssochoou, 2004), and so on.

Asymmetries and Symmetries

Interactional epistemology of social representations is an epistemology of changes between two opposite tendencies, for example: asymmetries and symmetries, disequilibria and equilibria, creativity/innovation, and conformity/consensus.

It has been well established that changes in physical and biological systems take place through alterations between symmetrical and asymmetrical states. Likewise, formation of knowledge, interactions, and relations between social agents involve, on the one hand, an effort for consensus. Individuals conform to one another make compromises with respect to their opinions and choices and, in general, shift their positions toward convergence in order to reduce conflicts. On the other hand, they may favor opposite tendency toward change rather than stability: breaking the symmetry works through tension, divergence, and differentiation between people, and even through conflict. Interaction breaks invariances. Individuals have a capacity to switch from asymmetry to symmetry, from equilibrium to disequilibrium, from conformity to innovation, and vice versa. The breakdown of symmetry initiates a dynamic order, an order that is evolving, encouraging innovative ways of thinking, differentiating and generating new patterns of knowledge, beliefs, images, and activities (e.g., Galam and Moscovici, 1994). Moscovici argues that the precondition for rationality and coherence of thought is not only collective consensus but that dissensus and contradiction are the other side of rational thought. Therefore, social psychologists must study not only conflict resolution, but also conflict arousal (Moscovici and Marková, 2006: p. 173).

In the study of psychoanalysis (Moscovici, 1961/1976/2008), asymmetries strongly dominate systems of communication like propaganda, diffusion, and propagation. For example, Moscovici's (1961/1976/2008: p. 334) concept of 'semantic barriers' retains specific asymmetries in contents and processes of diverse representations interacting with one another. Moscovici explored semantic barriers particularly in the relation between language and action in propaganda. In order to achieve transformation of beliefs in individuals propaganda creates a specific language by using qualified expressions and so changing meanings of words. Words that originally referred to certain representations as, e.g., psychoanalysis as a therapy, then referred, with a qualified expression 'American', to an alternative representation 'American psychoanalysis', which had an ideological and negative meaning. By distorting meanings of words, propaganda not only erects semantic barriers among groups, but it affects actions, creates conflicts, and postulates new ideologies (see Gillespie, 2008).

Heterogeneity and Cognitive Polyphasia

Language and communication as a point of departure in epistemology of social representations has yet another significance: to communicate means to take diverse routes, leading once to intersubjective understanding between individual and group, once to conflict, or to negotiation and compromise, or to a firm self-positioning. This implies transformation of one kind of knowledge into another one. Transformation of knowledge and messages is pertinent to specific social, historical, and cultural conditions.

One of the basic features of the theory of social representations is its focus on the dynamic coexistence of distinct modalities of thinking, which are present in communicative actions. They contribute to viewing the issue in question from diverse perspectives, which enable formulation of different arguments. Such communication-centered thinking involves a number of directions: it judges, evaluates, criticizes, makes proposals for action and raises controversial issues. Moscovici (1961/1976/2008) calls these diverse modalities of thinking and communicating 'cognitive polyphasia'. Cognitive polyphasia is characterized by tension, conflict, and constraint rather than by equilibrium and adaptation.

The concept of cognitive polyphasia is inherently dialogical. The divergent modalities of thinking are expressed as specific Ego–Alter communications to follow diverse mental paths. Cognitive and emotional goals employ heterogeneous modes of thought which may range from scientific to religious, from literal meanings to metaphoric interpretations, from jokes to formal expressions, and so on. They are suited to and articulated in contexts of which they are parts and in which speakers create links to others' communications, anticipating their responses, reactions, and feelings.

Following the original publication of 'La Psychanalyse' (1961/1976/2008), other researchers have presented many examples of cognitive polyphasia in common sense thinking (for reviews see, e.g., Duveen, 2007; Jovchelovitch, 2007; Wagner and Hayes, 2005). These include cognitive polyphasia in different cultures, daily situations, and various contexts.

Ethics

The theory of social representations places emphasis on humans as ethical beings who pursue passions and make ethical choices. Focus on making ethical choices (Moscovici, 1961/1976/2008) distinguishes the theory of social representations from other current social psychological theories as well as from natural sciences and from those social sciences that are based on deterministic and 'objective' theories.

Only if we describe humans in dialogical terms of the Ego–Alter, can we reasonably speak about relational notions like freedom, justice, solidarity, dignity, or forgiveness. Ego–Alter relations. They are characterized by openness toward multifaceted and heterogeneous realities and their relationships. These relations are never neutral: they are ethical, that is, evaluative and judgmental. This conception therefore preclude the separation of 'facts' and values. Moscovici (2011) traces historical attempts to rationalize and mechanize interpersonal relations, as well as the efforts to draw objectified and mechanistic rules into ethics.

In order to construct knowledge about one another, speakers complement their partial knowledge by imagining what the other could be like and what might be expected from him or her. Imagining could be also involved in an internal dialogue with the self, others, or with circumstances. Moreover, we act on the basis of imaginations created in our internal dialogues. I imagine something and get angry: imagination is communicative, it is dialogical. Words may convey specific images over centuries.

Ethical choices are particularly visible in ceremonies of name giving, bringing into the focus of attention ways, in which humans reinforce the importance of creations of new social realities and fix them in and through language; giving something a name means giving the thing a new content and meaning. This is an imaginative enterprise expressing ethical choices of the namer: it conveys hopes, it judges and condemns others, it evaluates. Names not only stabilize social representations but also initiate new ones. Moreover, by naming we impose limits, properties, and structures on the named object, person, or phenomenon. In order to amplify the impact of names we use metaphors as the ways of objectifying ideas and turning them to reality.

Figurative Scheme

A social representation is structured around a figurative scheme that underlies images, concepts, or judgments that a group or society has generated over time. A figurative scheme often takes the form of a dyadic antinomy. For example, we understand freedom in contrast to what we consider to be a lack of freedom; justice is understood through absence of justice; logos is contrasted with mythos, and so on. Antinomies are features of thinking, language, and communication in all cultures, but different cultures and societies employ their capacity of making distinctions and thinking in antinomies in specific ways. We find them throughout eons of human history both in scientific and in common sense thinking, although very often they are present implicitly without becoming an explicit discursive topic. Sociocultural changes, however, may bring implicit antinomies to the public awareness and into discourses, reflecting societal tensions and conflicts. This means that from that moment on, antinomies turn into 'themata', whether in scientific thinking where, according to Geoffrey Holton, they generate scientific theories, or in common sense thinking where they generate social representations (Moscovici and Vignaux, 1994/2000). Analyzing a figurative scheme in the case of ethnic minorities, e.g., gypsies, Moscovici (2011) shows it is articulated around the thema nomadic/sedentary. He argues that this thema is as basic as, for example, the thema left/right in social representations of political parties. A figurative scheme associates an ethnic minority with a number of themata that form mutually interdependent networks. For example, the thema pure/impure (clean/dirty) defines the minority's existence as a deviance within the native population. When the Spanish Inquisition introduced the racial concept of 'purity of blood', gypsies were regarded as a 'wicked nation of beggars and idlers' (thema diligent/lazy). However, they were Christians (Christians/Jews thema) and therefore, they were not expelled from Spain; but because they were impure, they could live only in specific places and were not allowed to leave those: "Blood was no longer evoked, but purity and impurity became concrete realities" (Moscovici, 2011: p. 455) and this was why they could not mix with the native majority.

Social Representations as Phenomena and as Interventions

The second meaning of social representations concerns concrete social phenomena that are part of daily life, of public discourses and that human agents continuously make and remake. In other words, in the process of re-presenting, individuals and groups act and intervene in life practices. This means that the theory of social representations assumes that when interacting, humans use resources from culture and traditions as well as from their living experience. Historical/cultural and contemporary resources may be in conflict, leading to disruption of routines, turning them upside down, and calling for action. Forces (e.g., commitments, attractions, etc. see above) between different kinds of Ego and Alter constitute a field for re-presenting complex social phenomena that are in the center of social life and social disputes, e.g., political, ecological, or health related. Such complex phenomena obtain their meanings in interdependence with and in relation to other representations within that culture and community. For example, the representation of democracy would be interdependent with other social representations within that particular culture, like representations of minority groups, of freedom of speech, economic situation of the country, and so on.

The relation between social representations and intervention practices is itself an object of research practice (Abric, 1994), e.g., of health research (Jodelet, 2006; Marková and Farr, 1995), education (Garnier and Rouquette, 2000), or politics. Intervention should allow for exchanges between traditional and new forms of knowledge, the preservation of culture, and its negotiation with emerging alternatives in

society (Jodelet, 2013). Doise (2002) regards social representations of human rights as interventions into social relations, whether these concern relations between individuals and groups or individuals and institutions. Human rights must be clearly defined precisely because they are interventions of one kind or other. Intervention strategies for the improvement of the quality of life would depend on a number of issues like the meaning of well-being, of life satisfaction, social welfare, as well as economic possibilities. Throughout his career, Moscovici has persistently insisted that the theory of social representations is – or should be treated – as anthropology of contemporary culture. Cultural anthropologists are concerned with the totality of life of social groups under study – that is, with beliefs and knowledge, myths, images, as well as with social practices in daily living. To understand these phenomena, it is necessary to study them in relation to one another, like meaningful wholes, rather than as independent elements.

Formation and Transformation of Social Representations

Let us now evoke the two basic processes that generate social representations: anchoring and objectification (Moscovici, 1961/1976/2008, 1984). In and through anchoring and objectification individuals and groups conventionalize objects, persons, and events by categorizing them and giving them distinct and shared meanings.

Anchoring is the process that familiarizes the strange phenomenon by classifying and naming it. Naming and categorization is not a neutral process but it involves judgment, evaluation and imagination; in other words, it is ethical. It builds on past knowledge, beliefs, and images. By anchoring humans reveal their theories about others, e.g., about a particular ethnic group.

Objectification is a more in-depth process, infusing anchored phenomena with a concrete reality. The idea of objectification is effectively expressed in Moscovici's claim that the phenomenon that is originally perceived in the process of anchoring becomes, in the process of objectification, conceived, that is, it becomes conceptualized as real. The interdependence and transformation of the anchored, i.e., the perceived phenomenon into an objectified, i.e., a conceived phenomenon, can be observed particularly in language. Naming embraces both anchoring and objectification. For example, the term like Freud's 'Oedipus complex' may be originally perceived as a strange and intellectual phenomenon and becomes associated with, or anchored to, the boy's jalousie of his father. Subsequently, through the use of 'Oedipus complex' in daily language, the term becomes objectified. It turns into designated ways in which relations between parents and children are organized, and it helps to interpret certain tensions in such relations and to refer to them as pathological symptoms. In other words, elements of scientific terminology turn into signs that correspond to a particular reality and become reified within that reality. Thus we may say about someone that he/she is stubborn or quarrelsome; through repeated use in language this label becomes conceived as a real feature of that person and subsequently, this 'reality' becomes incorporated into habitual social practices with respect to that individual.

Graphic representation is another form of objectifying ideas into entities. Written texts, posters, or pictures, all turn an idea into real graphic objects. Visual images in the press, advertisements, and campaigns are used to influence or change social representations of political or health issues. Visual images in the press have been particularly influential in staged photographs capturing public images about genetic engineering as injecting tomatoes with genes that make them grow bigger. Wagner and Hayes (2005: p. 181) comment that viewers associate images of genetically modified tomatoes with inoculation and with injecting foreign materials into human bodies as they know it from medicine and chemistry. There is also a related belief of infection that passes from one organism to another. These examples show that a new reality and new social representations are created by means of semiotic signs and symbols and their transformation.

We have already noted that one of the fundamental features of human thinking is making distinctions and understanding phenomena as antinomies, and that a figurative scheme of the representation often takes the form of a dyadic antinomy – or a thema. Themata that generate most social representations are those pertaining to the Ego–Alter, like private/public, morality/immorality, justice/injustice, and freedom/oppression, among others. Such themata are in the heart of social sciences, and they generate social representations of phenomena like democracy, citizenship, quality of life, and health and illness, to name but a few. Here we come to the point that links themata with anchoring and objectification. Many antinomies are implicitly present in common sense thinking for centuries, and they may never be brought to explicit awareness. However, when a new and strange phenomenon is perceived it may become anchored to such an implicit dyadic antinomy. For example, the emergence of HIV/AIDS in the 1980s anchored this disease to morality/immorality and led to the creation of a new figurative scheme. The existing relational category of morality/immorality became rethematized and it objectified new contents, values, images, and has generated a social representation of a newly emerged object, i.e., of HIV/AIDS. A social representation is rarely generated from a single thema; in the case of HIV/AIDS, rethematization of morality/immorality has been associated with rethematization of social values related to sexuality, promiscuity in the general public, discrimination of minorities, and social recognition, among other issues. Although the antinomy morality/immorality itself has not been questioned, the content and context of morality/immorality has been differently thematized in different fields (see above) in which the social representation of HIV/AIDS has been engaged. For example, the question of personal and social responsibility, medical confidentiality, and human rights all became part of discourse in such specific fields. Communicative processes, through which these changes in meanings are usually achieved, carry symbols and images, which not only circulate in public discourses but also organize and generate discourses. They shape common thinking, language, and behavior, and provide grounds for the formation of new social representations.

Different Approaches to the Study of Social Representations

Following the publication of 'La Psychanalyse', social representing has been studied in various social, political, health-related, and other kinds of phenomena circulating in public discourse (for a comprehensive review, see Wagner and Hayes, 2005). Explorations of social representations have become widely differentiated. As a result, researchers now speak about social representational approaches – or schools of social representations – rather than about a single theory. For example, there is the Aix-en-Provence school based on structuralistic approach that emphasizes central nucleus and periphery of representations (e.g., Abric, 1994; Guimelli, 1994), whereas the Genevean school of Doise specifies organizing principles of social representations (Doise, 1986). Other approaches are anthropological and cultural (e.g., Arruda and de Alba, 2007; Chryssochoou, 2004; Jodelet, 1989/1991). Still others (Wagner and Hayes, 2005; Duveen, 2007) bring to attention the role of social construction and discourse; and Valsiner draws on the role of semiotic mediation and social experience (e.g., Valsiner, 2003). In addition, one can hardly discuss social representations and culture without foregrounding language, communication, and, more specifically, dialogicality as a major feature of the relation between social representations and culture (Marková, 2003/2005; Valsiner, 2003).

Methods of Studying Social Representations

The growing interest in theoretical and empirical research in social representations also highlights its challenges. Many studies, in order to explore social representations of specific phenomena, use *inductive and deductive* methods, and they assimilate social representations to research based on traditional epistemology and on using statistical methods by proving of disproving hypotheses. In contrast, Moscovici argues that surprising findings in research come from discovery and invention rather than from inductive methods by proving hypotheses (Moscovici, 1992).

The difference between method of proof and method of discovery draws attention to the fact that in the latter, the researcher must examine the social representation of the phenomenon (e.g., of psychoanalysis, of AIDS) as interdependent with the relevant situation (e.g., social, historical, political). If we consider Moscovici's study of psychoanalysis, we find that historical, political, and social forces of these studies are just as important as interviews and observations of activities in which the participants were involved. They both constitute the field (see above); they are studies of single cases. Generalization based on single case studies is of a different nature than inductive generalization. In using a single case study one does not generalize the findings to a population but to the theory of the studied phenomenon. Moscovici (1961/1976/2008: p. 175) speaks about 'analogical generalization', which does not refer to generalization to populations as in inductive research. Instead, it refers to the possibility of transformation of one kind of knowledge into another one, using a preliminary theory of the phenomenon in question. The study of psychoanalysis captured social representations during a cultural fight between ideas expressed by the Catholic Church and the strong Communist Party in France in the late 1950s and early 1960s. In this single historical event, it was the coexistence of strong contradictory forces that interacted with common sense thinking that generated social representations of psychoanalysis. However, the findings from this single historical event with respect to different kinds of intellectual polemics, forms of thinking and the clash with established values are transferable to other kinds of social representations – or we could say – to the class of events represented by that case. The forces that form the field do not leave any of the components stable over time, whether the data gathered from participants (interviews, the media) or the data constituted by the relevant historical, political situations, and cultural diversities. Of course, this does not mean that the researcher should not study attitudes or opinions using inductive techniques. Researchers have many choices and it is fully legitimate to use survey, experiments, or any other methods in order to study specific questions, as long as the researcher realizes that it could be problematic to call such research a study in social representation. Implicit knowledge and unconscious processes are characteristics of the human mind just as much as explicit knowledge and conscious processes; equally, implicitness and unconsciousness are features of dialogicality and of the theory of social representations.

Reproduction and Cultural Anthropology

Abstract

Reproduction is central to contemporary anthropological theory, intersecting with studies of kinship, biomedicine, exchange, sex, gender, politics, nature, and capitalism. The production of reproduction as a category and its domaining as feminine, private, and biological was central to the modern Euro-American separation of industrial wage labor from domestic labor and care, that is, between reproduction and production and between nature and culture. Feminist anthropology of the 1970s called for a focus on women's lives, laying the foundation for an explosion of interest in reproductive experience, as well as critique of the category itself, as both natural and naturally private and female.

Reproduction is central to contemporary anthropological theory, intersecting with studies of kinship, medicine, science, exchange, sex, gender, politics, nature, disability, capitalism, life, humanity, morality, and temporality, to name a few. This has not always been the case. Until recently, reproduction was dismissed as apolitical and irrelevant to the 'big ideas' of anthropological theory, associated as it is with women – what their bodies and biologies do to have and care for children – through menstruation, conception, gestation, childbirth, nursing, and menopause (Taylor, 2004). In Europe and North America, these reproductive processes have tended to be understood as making individual, new people, within the private, intimate domain of heterosexual coitus, separate from political and economic life.

The production of reproduction as a category and its domaining as feminine, private, and biological was central to the eighteenth- and nineteenth-century Euro-American separation of modern, industrial wage labor from domestic labor and care, that is, between reproduction and production and between nature and culture. In the late nineteenth century, this productive/reproductive division shaped the ideal unit into a couple, consisting of an active, public, productive male and a coy, domestic, reproductive female whose intimate reproductive capacities required intensive surveillance and regulation. Although the domaining of reproduction as private, feminine, and biological makes it seem nonpolitical, some of the fiercest political battles of the nineteenth, twentieth, and now twenty-first centuries such as population control, the regulation of prostitution, homosexuality, abortion, and the beginnings of 'life' have been reproductive.

Early anthropologists' investigations of what we now call reproduction were part of the study of kinship among primitives. With hindsight, it is apparent that these investigations said as much about the Euro-American organization of reproduction (as private, biological, and female) as they did about the lives of their subjects and objects of study. Kinship then, through the mid-twentieth century, was the study of how primitive peoples culturally organized their natural reproductive processes, reinforcing the divide between nature and culture, which informed so much of the twentieth-century anthropological project.

Feminist anthropology of the 1970s called for an increased focus on women's lives, laying the foundation for an explosion of interest in reproductive experience, as well as critique of the category itself, as both natural and naturally private and female. More recently, cultural, medical, and feminist anthropologists have begun to trace the entanglements of the material world and symbolic processes; thus the study of reproduction has expanded to include informatics and artificial life, regenerating earlier connections between reproduction and production. These studies are part of a larger shift in cultural anthropology toward including the material and biological world as important objects of study, challenging the assumption that there is a multiplicity of cultural means to organize a singular set of underlying universal and fixed biological processes. This article, then, is about the anthropology of reproduction, but also, importantly, about how both anthropology and reproduction have been constitutively shaped as categories within a modern cosmology that claims that the world is divisible into separate spheres.

The Nature of Reproduction and the Culture of Kinship

Feminist historians and anthropologists describe how the concept of reproduction is thoroughly embedded in the immense shifts wrought by the industrialization of Europe and North America, which radically reconstituted relations and essentialized, as natural and apolitical, new distinctions between humans and nonhumans, women and men, adults and children, as well as classes and races (Daston, 1998; Foucault, 1990; Latour, 1993). The word 'reproduction' came into common use in the eighteenth century, and emphasized abstracted, non-agentive, biological processes as distinct from production, which was increasingly understood as agentive, mechanical, and male (Jordanova, 1995). Through the development of the biological sciences, reproduction came to be naturalized and universalized as a set of processes that take place in individual bodies, especially the bodies of women. The nuclearization and privatization of family groupings through capitalist wage labor resulted in the conflation and marginalization of women's reproductive abilities and sexuality, as well as the association of children with mothers instead of fathers, and the exclusion of other important kin relationships (like siblings) from productive–reproductive processes. Although the domestic reproductive sphere was crucial for the continuance of capitalist production,

and the domain through which private property was transferred, the family, especially women and children, became the sentimental 'haven in a heartless world,' which required protection from the economic rapaciousness of the (male) market (Lasch, 1977). The productive–reproductive division had far-reaching effects, such as making economic calculations in relation to family life offensive to bourgeois propriety, and making women, as newly noneconomic actors, into nonpolitical subjects (Jordanova, 1995; Kant, 1949).

One of the key projects of early twentieth-century anthropology was to understand how 'natives' organized themselves when they seemed to have no political systems: a lack that served as a rationale for the colonial civilizing project and a means for further anthropological distinctions between the West and the rest. Thus, instead of political systems, anthropologists found kinship systems among the primitives they studied (Franklin, 1997). A central puzzle became why these kinship systems did not match the 'facts' of biological reproduction, or biogenetic assumptions as they had been established in eighteenth- and nineteenth-century Europe and codified through Darwinian evolutionary theory. Within nineteenth century and early twentieth century models of unilinear cultural evolution, then, accurate knowledge of biological reproduction, most importantly paternity, was a step toward civilization. Primitive people, the story went, organized their kinship culturally, while Euro-Americans recognized their relatedness through natural biological principles, furthering the formative anthropological divide between nature and culture (Degler, 1991; Franklin, 1997; Weiner, 1995). This distinction between the nature of reproduction and the culture of kinship played out in Bronislaw Malinowski's classic ethnographic work in the Trobriand Islands (Malinowski, 1932). Malinowski argued that Trobrianders did not understand the true link between coitus and conception or recognize biogenetic paternity, believing instead that spirits inseminated women, a formulation that shaped the twentieth-century anthropological division between natural and social facts (Weiner, 1995). Malinowski's account set off the heated mid-twentieth century 'virgin birth debates' about the ability or inability of Trobriand natives to understand reproductive processes. While anthropologists like Edmund Leach and Melford Spiro argued about what the natives knew, they never examined how situated the biological facts of life were within the social, political, and economic conditions of late nineteenth-century Europe and North America (Franklin, 1997). As several recent feminist anthropologists have pointed out, Malinowski's claim was based on his assumption that coitus is the one and only reproductive act, which was itself different from earlier European models of conception, that for instance saw female orgasm as essential to conception or conception as a more environmental process (Weiner, 1995). Malinowski's Victorian–Darwinian model of conception also assumed maternity as much as paternity, whereas in the Trobriands neither men nor women were seen as generators of children, although both contributed to their being. Furthermore, while Malinowski's Trobriand work incorporated theories of exchange as well as reproduction, his male-centered biogenetic assumptions prevented him from noticing how women's power came through siblings, especially sister/brother dyads, that linked reproduction to economic and cosmological relations. As Weiner argues, in the Trobriands, the organization of these relations was not about nature but about power, and gender-based power was not only or even primarily constituted through the intergenerational transmission of substance, but through siblings' exchange relationships (Weiner, 1995).

The model undergirding Malinowski's analysis, where kinship is the cultural means to organize biological reproduction, is omnipresent in some of the twentieth century's most celebrated kinship studies (Franklin, 1997). To name just two: Lévi-Strauss's model of exchange as the origin of social life never departs from the biogenetic assumption that defines kinship and society as the exchange of control over women's biologically ordained procreative role (Lévi-Strauss, 1969). This model posits women as only reproducers and ignores how intergenerational relationships can be produced outside of heterosexual marriage through sibling relations and larger kin groupings (Rubin, 1975; Weiner, 1995). And even while David Schneider's account of American kinship was crucial to the emergence of critical feminist studies of kinship and reproduction, his model preserved the distinction between fixed natural reproductive facts and malleable social facts (Schneider, 1980). An assumption underlying both of these classic kinship studies is that the biological nature of reproduction remains outside the purview of scholarship in cultural anthropology. Reproductive processes remained under-theorized on two counts; as both biological and female, reproduction was not cultural or political.

The Anthropology of Reproduction: 1980–2000

Feminist anthropologists from the 1970s on shifted anthropology's attention to women's lives and experiences, which facilitated a florescence of research on reproduction in cultural anthropology. For the most part, these studies have demonstrated how reproduction – which can seem so private, personal, intimate, medical, natural, and biological – is thoroughly political and economic, serves as a key site of global processes, and is saturated with stratifications of race, labor, class, and sex (Jordanova, 1995). 'Making reproduction central to social theory,' which is exactly what Rayna Rapp and Faye Ginsburg did in their formative edited volume *Conceiving the New World Order*, allowed for a reexamination of some of the most long-standing theoretical debates in anthropology: the relationship of nature to culture, of production to reproduction, between the individual body and the body politic, and the examination of how power works, making reproduction a vital category for anthropological understanding of the world (Ginsburg and Rapp, 1995: p. 1).

Late twentieth-century anthropological studies of reproductive processes and practices – such as pregnancy, abortion, the treatment of infertility, birth control, adoption, conception, miscarriage, sterilization, the collection of vital statistics, the analysis of demographic trends, the codification of the categories of maternal and infant mortality, birth, menstruation, menopause, the medicalization and individualization of reproductive processes, reproductive technologies, parenthood (both same-sex and heterosexual), and child-rearing – used several intertwined theoretical approaches, especially political-economic and poststructuralist accounts that examine

configurations of power, knowledge, and subjects. Anthropologists have shared these approaches with historians, sociologists, literary critics, and political scientists, as they serve to construct critical genealogies of the Euro-American historical formations that produced the emergence of the category of reproduction (and anthropology, for that matter). In addition, anthropological accounts of reproduction have also tended to be comparative, a method specific to anthropology, which has served to denaturalize the category of reproduction itself and its near-automatic association with the female, the private, and the biological.

Political-economic approaches to reproduction often focus on the transformation of Western Europe to modern industrial capitalism, which reorganized social life through distinctions between production and reproduction, private and public, the economic and the domestic, and the intensification of the globally unequal distribution of material resources. Much of the recent literature on the relationship of contemporary consumptive practices to the reproduction and personhood of children takes its cue from the historical shift between productive children, who contributed to household economies, and priceless children, who are consumed for by their parents (Anagnost, 1995; Layne, 1999; Taylor et al., 2004; Zelizer, 1994). Emily Martin's cultural analysis of reproduction linked narratives and experiences of conception, birth, and menstruation in the United States to contemporaneous modes of production throughout the twentieth century (Martin, 1992). One of the principal political economic concepts in the literature has been that of 'stratified reproduction,' a term coined by Shellee Colen to describe "the power relations by whom some categories of people are empowered to nurture and reproduce while others are disempowered" (Ginsburg and Rapp, 1995: p. 3). The concept has been taken up widely, used within Colen's own work on West Indian nannies working for affluent families in New York City and in recent work on transnational surrogacy in India (Colen, 1995; Whittaker, 2010).

The development of medical anthropology in the late twentieth century is crucial to understanding the emergence of the anthropology of reproduction. Medical anthropology began as an applied endeavor, in which anthropologists assisted biomedical, public health, and development experts, both internationally and domestically, in understanding how cultural context contributes to underlying biological etiologies of ill-health (Foster and Anderson, 1978). Over time, more critical strains of medical anthropology developed. One critical framework examines the political-economic relations of the global distribution of health care (Singer and Baer, 1995). The analysis of maternal mortality as a key indicator of social and economic inequality is central to this approach, which seeks to address public health and biomedical experts within their own language and categories, in order to affect policy and reduce health inequalities (Berry, 2010; Janes and Chuluundorj, 2004). Another critical medical anthropological framework has been to examine the production of these powerful categories themselves, such as maternal and infant mortality, women's reproductive health, and reproduction, using both political economic analysis and poststructuralist approaches to the production of knowledge claims and their effects in the world (Adams, 2000; Adams and Pigg, 2005; Scheper-Hughes, 1992). Currently, medical anthropology is constituted through tensions between these two related but disparate frameworks (Fassin, 2012). Although the former framework undoubtedly has more effects on health policy outside of anthropology, the rest of this article will focus primarily on the latter because it offers a better means to examine the elaboration of the category of reproduction within anthropology itself.

A vast number of anthropological studies of reproduction combine political economy with poststructuralist analysis of how biology came to have no politics, producing subjects whose roles were naturalized in the political-economic order. By the late nineteenth century in Western Europe and North America, the domain of what we think of as reproduction was formulated and regulated in the name of increasing the life and health of populations (as working and fighting forces) through heterosexual reproduction, understood as natural biological processes. Practices that were understood to impede the right kind of reproduction, such as childhood masturbation, prostitution, homosexuality, abortion, and the use of birth control, were codified, managed, or outlawed for the first time. To account for these transformations, the social theorist Michel Foucault developed the term 'biopower' to describe how scientific medicine deemed as apolitical became a powerful tool for governance in post-Enlightenment Europe. Through the codification of sex and race as innate and natural, the newly biological body became embedded within increased regimes of surveillance (Foucault, 1990). As the philosopher Judith Butler contends, "The materialization of bodies as matter-prior-to-power is in fact power's greatest effect" (cited in Murphy, 2011: p. 24). These insights about power as deriving from knowledge of the natural world, deemed apolitical, have greatly influenced many of the scholars working on the regulation of reproduction through the vital politics of abortion, embryos, population control, eugenics, birth control, women's reproductive health, and life itself (Casper, 1998; Erikson, 2001; Ginsburg, 1998; Landecker, 2003; Mamo and Fishman, 2001; Morgan, 2009; Rapp, 1999). Many of these studies analyze these practices through the framework of medicalization, which describes how processes come to be understood and managed through a primarily medical lens, which brackets the political and social world.

While Foucault delineated biopower through sex, several theorists have pointed out that sex as a domain is somewhat different now than in the late nineteenth century, partly because biological reproduction can occur through other means than heterosexual coitus (e.g., *in vitro* fertilization (IVF), artificial insemination) and there are now more means to prevent conception within coitus (Rabinow and Rose, 2003; Strathern, 1992a). Given the Euro-American truism that coitus is essential for reproduction, there is surprisingly little overlap in the study of sex practices in relation to reproduction. Perhaps the paucity of focus on sex acts in the anthropology of reproduction arises from the way power imbalances across sex, race, and class have contributed to many forms of troubling heterosexual sex, like rape, that also trouble reproduction (for a rare exception, see Weismantel, 2004). While there are relatively few studies that investigate sex acts of any kind in relation to reproduction, the critique of the naturalization of reproduction to women – for example, the collapse of all of 'women's health' to 'reproductive health' – has compelled a burgeoning literature on male

reproduction, connected to larger moves within gender studies that examine how men continue to be the unmarked sex (Dudgeon and Inhorn, 2004; Gutmann, 2007; Inhorn, 2006).

Contestations over homosexuality (understood as nonreproductive sex) and assisted reproduction (understood as nonsexual reproduction) in Europe and North America in the last decades facilitated a resurgence of interest in kinship in anthropology (Franklin and McKinnon, 2001). Queer kinship and same-sex parenting, in connection with the recently expanding literature on care, have contributed to anthropologists' ability to analyze the specificity of heterosexual, genealogical reproduction (Borneman, 2001; Lewin, 1993). Likewise, reproductive technologies like IVF and egg donation allow anthropologists to examine reproduction outside of heterosexual intercourse as well as investigate how assisted reproduction has combined both the natural and the artificial, established, and distinct domains since the eighteenth and nineteenth centuries (Strathern, 1992b; Thompson, 2005).

In the industrialized world, consisting of settler nations and nation-states made wealthy through colonial capitalism, the wrong and right kinds of reproduction were often defined through biological race, which continues to shape policy and practice within nations and transnationally, especially in the realm of international population policy and migration (Fraser, 1995; Goldade, 2007; Morgan and Roberts, 2012; Pashigian, 2009). Nineteenth- and twentieth-century battles about slavery, miscegenation, immigration, population control, female sexuality, eugenics, and Nazism, which played out on national and international stages, intertwined through apprehensions about the reproduction of cheap labor, the distribution of resources, and the intractable or mutable nature of groups deemed to be fit or unfit reproducers (Douglass, 2005; Horn, 1994; Nouzeilles, 2003; Stepan, 1991). Even though race is by no means a universal form of human organization, the ubiquity of governance through biological reproduction tends to avail itself of the specific stratifications that maintain the hierarchies at work within and between nation-states. And while having and caring for children has not been universally practiced as a private domestic matter governed through medicine, increasingly states outside of North America and Western Europe codify and govern reproduction as a biological matter of great interest to the nation (Greenhalgh, 2008; Tarlo, 2003; Unnithan-Kumar, 2004).

Along with historians, sociologists, and political theorists, anthropologists have illuminated how reproduction became a crucial site of governance within Euro-American politics and economics that simultaneously produced individual bodies filled with apolitical, universal biological processes. In addition, the anthropology of reproduction engages in comparisons demonstrating how having and caring for children has been organized and experienced outside of a Euro-American reproductive framework, which provide a means to see how categories, institutions, and practices arise in particular times and places. Anthropologists usually make these comparisons between people in the nonindustrialized or the developing world and Euro-Americans, although increasingly they make comparisons outside of this particular dyad. Comparisons are fraught with difficulties because of the tendency to see differences as natural, timeless, and fixed, and most problematically as arising separately from one other – as though the historical, economic, and environmental processes that shape one place do not shape another. Through comparison, though, some of the twentieth century's most heated controversies involving reproduction have been made explicable and local, allowing for recognition that there could be other ways of organizing the world.

One of the central insights of these studies is that while reproduction seems to be located in individual families in Western Europe and North America, it is often organized as explicitly collective in nonindustrialized locations, whether on the scale of the extended family, village, community, region, or nation. Another more recent insight parses how key theoretical innovations in the mid-twentieth century, such as gift exchange (Levi-Stauss, Mauss) and the symbolic ritual process (Victor Turner, Van Ganep), were based on practices narrated by male anthropologists as magico-religious childbirth and conception rituals, understood as nonpolitical. With reanalysis, these accounts demonstrate the absolute centrality of these processes to political life in nonindustrialized settings.

Anthropologists have analyzed practices like adoption, abortion, birth, and assisted reproduction to great comparative effect. The comparative examination of adoption and child circulation has contributed to insights into the Eurocentric privileging of intergenerational biogenetic ties, whereas the circulation of children often reinforces material care relations between a larger group of adults as much as the reproduction of children (Leifsen, 2010; Leinaweaver, 2008; Modell, 1995). Pregnancy and childbirth are two other realms where comparison demonstrates how a process deemed natural and universal in Euro-American contexts is thoroughly shaped within the material semiotic and relational context where it is situated (Boddy, 1998; Ivry, 2010; Jordan, 1997; Morgan, 1989; Pinto, 2008; Van Hollen, 1998). The anthropological literature on abortion and personhood provincializes North American debates about when life begins as local and specific, since personhood in different non-Western sites can commence at various times, often post-birth, and the concept of individual life is not relevant to how children are made at all (Browner, 1976; Conklin and Morgan, 1996; Kaufman and Morgan, 2005; Picone, 1998).

New reproductive technologies have been an especially rich site for comparative work on reproduction. Starting in the early 1990s, Marilyn Strathern used her ethnographic delineation of relational personhood in New Guinea to analyze how the Euro-American use of assisted reproductive technologies (ARTs) is based on (1) the formulation of a domain called reproduction within the separation of the natural and the artificial (2) configured through persons as (3) unique individuals (Strathern, 2005). Strathern's work opened up a vast array of comparative questions for current ethnographers of reproduction (Bamford, 2007; Franklin, 1997; Roberts, 2012a). Ethnographers who study the use of ARTs outside of Europe and the United States, and those who have made comparisons within Europe, have contributed to an increasing sense of the specificity of reproduction within particular political, economic, and religious contexts (Bharadwaj, 2002, 2006; Inhorn, 2003; Kahn, 2000; Melhuus, 2003).

As a whole, anthropological comparison demonstrates that the biological processes involved in having children are not universally organized under the heading of reproduction.

This insight resonates with recent critical work in medical anthropology and science technology studies that diffuse and redistribute the self-evident nature of reproduction by examining how biological processes themselves are shaped through historic, economic, and political realities.

Reproduction Constructed

The cultural anthropological work of the late twentieth century, which sought to bring reproduction into the heart of anthropological social theory, delineated the political and economic processes that affect reproduction and the centrality of reproduction to social life. While much of this scholarship made an implicit distinction between biological and cultural processes, this work also made it possible to trouble the categories of nature and culture that shaped how reproduction was framed through the twentieth century (Franklin, 1995). This troubling has taken on new forms in the last decades through the work of scholars who examine the history, politics, and economics of biological processes themselves and by decentering the individual body as the central site of reproduction. These scholars, whom I loosely categorize as constructionists, in distinction to social or cultural constructionists, do not assume that diverse malleable cultural processes sit on top of fixed and universal biological processes, but instead insist on parsing the specific, material, semiotic relations between people and the worlds they inhabit without seeking to classify them a priori as nature or culture.

Margaret Lock's seminal book *Encounters with Aging* (Lock, 1993) was an early example of a constructivist approach. Through an intensely comparative study of menopause in Japan and Canada, Lock observed that while women in mid-twentieth- century Canada and women in mid-twentieth century-Japan both cease to menstruate in midlife, the endocrine changes associated with menopause in North America are by no means universal. At the time of her study, women in Japan did not experience hot flashes. Lock argued that women residing in these different nations possessed 'local biologies,' constructed within fields of thick historical and economic relations (for further uses of 'local biologies,' to explicate reproductive processes, see Behague, 2002; Roberts, 2012b).

In a related vein, Sarah Franklin draws our attention to how embryos produced in laboratories, along with heart valves and skin, are not only 'born and bred, or born and made, but made and born' through rigorous quality control that takes away impurities, making these lab-made entities as 'good as nature' (Franklin, 2006: p. 171). In moving away from the "dichotomizations of social and natural facts" (Franklin and Ragoné, 1998: p. 3), scholars have begun to link reproduction to informatics, biocapital, intellectual property, and genetic engineering (Helmreich, 1998; Waldby and Mitchell, 2006). These linkages between human reproduction and the contemporary means to engineer biological processes collapse distinctions between nature/culture and production/reproduction.

Collapsing nature/culture works in conjunction with other collapses like that of the surety that reproduction works in individual bodies. As the feminist philosopher of science Donna Haraway argues, reproductive technologies are not only expensive technomedical procedures that treat individual women's bodies, but complex economic and biological processes that make diaper pins, home birth, accounting techniques, population politics, breast milk, and baby formula (Haraway, 1997; Haraway and Goodeve, 2000). Taking her cue from Haraway, feminist historian of science Michelle Murphy argues that if we ask "Where does biological reproduction reside?" the answer "the body" is simply not up to the task (Murphy, 2011). Murphy's framework of 'distributed reproduction' allows us to examine "what counts as biological reproduction by tracking the dispersion of sexed living beings into their infrastructural and political economic milieu." The framework of individual bodies and universal biological processes is not up to the task, for instance, of understanding why among the Aamjiwnaang, First Nations peoples living near the chemical alley of Sarnia in eastern Canada, only 35 boys are born for every 100 girls. To grasp reproduction in this case, we need to trace the specific tangles of technoscience, nation-states, capital, the malleable and vulnerable endocrine processes of fish and people, the fluid dynamics of rivers, the techno-assemblages of chemical manufacture, population politics, and tax breaks. While twentieth-century anthropology excelled at describing the collective nature of cultural practices that coalesced around reproductive processes outside the West, much of the recent constructionist work on reproduction expands the members of the collectives everywhere beyond people to include policies, chemicals, waterways, and fish in all their relational ontologies. Through this lens, reproduction becomes a useful and constructed domain requiring a broad analytic lens to more fully account for the wide array of actors and processes involved in its production.

Conclusion

Within anthropology before the last decades of the twentieth century, "reproduction could be described as invisibly central (along Darwinian, patriarchal, and biologically determinist lines), while remaining visibly marginalized (for example, in terms of childbirth practices)" (Franklin and Ragoné, 1998: p. 3). The situation has changed. Foregrounding reproduction as a useful conceptual domain, instead of as a universal biological process residing in unique, bounded, individuals, has been a key anthropological innovation, allowing anthropologists to transform how we constitute our objects of study, what questions we ask, and how we collaborate across fields if productive/reproductive and nature/culture divides no longer configure the boundaries of our discipline.

Abstract

This article argues that a not so sharp distinction between affluent and developing nations in terms of understanding of and challenges for the realization of reproductive rights and examines intersections and disjunctions in relation to sexual rights. It charts the many challenges in contemporary politics of human rights in the domains of reproduction and sexuality in terms of enabling conditions required for the realization of these rights, the growth of religious dogmatic reactions to these claims, the scalar developments in biomedicine and biotechnology.

Introduction

In 1994, the Program of Action of the International Conference of Population and Development (ICPD Cairo, 1994) defined reproductive rights as:

> [Embracing] certain human rights that are already recognized in national laws, international human rights documents and other consensus documents. These rights rest on the recognition of the basic right of all couples and individuals to decide freely and responsibly the number, spacing and timing of their children and to have the information and means to do so, and the right to attain the highest standard of sexual and reproductive health. It also includes their right to make decisions concerning reproduction free of discrimination, coercion and violence.
>
> Paragraph 7.3, United Nations, 1994

The ICPD Program of Action also defined abortion as a major public health problem and strongly recommended that when legal it should be safe and accessible (Paragraph 8.25). A year later, the Platform of Action of the IV World Women Conference (IV WOW Beijing) reaffirmed these ICPD principles, adding the recommendation that countries should revise existing punitive legislation on abortion. The Beijing Platform of Action also spelled out the substantive contents of women's sexual rights:

> The human rights of women include their right to have control over and decide freely and responsibly on matters related to their sexuality, including sexual and reproductive health, free of coercion, discrimination and violence. Equal relationships between women and men in matters of sexual relations and reproduction, including full respect for the integrity of the person, require mutual respect, consent and shared responsibility for sexual behavior and its consequences.
>
> Paragraph 96, United Nations, 1995

In 20 years since these definitions were adopted the language referring to reproductive rights and abortion has not been substantially altered. On the other hand the interpretation, use, and application of sexual rights have decidedly expanded beyond women's human rights and the heteronormative imprint of the second sentence of Paragraph 96 has been contested and deconstructed. Although no new text has been agreed upon in intergovernmental negotiations, the work of human rights bodies and authoritative experts gradually construed a revised definition of sexual rights that reads as follows:

> Sexual rights include the right of all persons to express their sexual orientation, with due regard for the well-being and rights of others, without fear of persecution, denial of liberty or social interference.
>
> Paul Hunt, Special Rapporteur on the Right to the Highest Standard of Health – United Nations E/CN.4/2004/49, 16 February 2004, paragraph 54

This article focuses fundamentally on reproductive rights and does not examine exhaustively the contents and challenges more specific to sexual rights in a broader sense. But it charts aspects of the trajectory of sexual rights, particularly in relation to sexual orientation and gender identity as they relate to parallel developments in reproductive rights, and it also briefly explores the intersections and distinctions between the two concepts. However, important aspects of sexual rights such as those related to sexual violence in its various forms, genital mutilations or sex work are not examined in depth.

Historical Trajectories: Longer Cycles and Close Antecedents

In the sober rooms of the International Conference of Population and Development in Cairo in 1994, many state actors were taken by surprise when rights claims in relation to 'sex' erupted. However, intertwined linkages between sexuality, gender, and reproduction have always been central to societal regulation across time and cultures. While reproductive and sexual rights belong to the liberal legacy of human and citizenship rights, they also call upon the foundational premises of freedom, equality, privacy, nondiscrimination, and dignity to contest the persistent patriarchal, androcentric, heteronormative bias of the modern social contract (Corrêa et al., 2008).

The meanings of sexual and reproductive rights claims must be examined in relation to the other forms of social

control and discipline that underlie the modern social contract, the apparatuses of societal regulation based on demography, biomedicine, criminology, and economics that also took form in the transition to Western modernity. Reproductive and sexual rights are intrinsically linked to biopower and biopolitics, as defined by Michel Foucault (1978). Early concerns with population size and dynamics, in particular the eighteenth-century Malthusian thesis on high fertility among the poor, would be persistently reactivated in the course of twentieth-century debates, including the Cairo Conference; its imprints have not vanished from contemporary policy concerns (Corrêa et al., 2013).

Biopolitics also implied concerns with the 'quality' of populations in particular in relation to 'race,' a notion that was made scientific in the nineteenth century and thereafter occupied a nodal place in the ideologies of nation building, homogeneity, and colonialism in Europe and the United States. Techniques of social and biological 'improvement' construed sex, gender, and reproduction as key pivots of regulation.

These modern juridical, legal, and infrajuridical apparatuses of regulation and discipline worldwide would be transplanted, at varying paces and degrees of intensity, to colonial territories. Colonial laws criminalizing abortion and sodomy that remain in the books in a large number of Southern postcolonial states are glaring examples of this transplantation (Sanders, 2009; ILGA, 2012). The profusion of hygiene and public health norms and interventions promoted by colonial administrations from the mid-nineteenth century has formed the basis for public health discourses and institutions incorporated by the early independent states in Latin America and later on by those emerging from the post-World War II wave of decolonization.

In the early nineteenth century the writings and experiments of Utopian socialists first combined economic and sexual justice. Later Engels (1884) analyzed the articulation between sex and economics in *The Origin of the Family, Private Property, and the State*, opening a pathway followed by socialist feminist pioneers like Emma Goldman and reaching as far as the 1960s feminist wave.

Concurrently, under the impact of Darwin's (1871, 1859) theories on sex reproduction and evolution of species, the 'science of sex' was invented and with it the concepts of sexual instinct and homosexuality. While most new 'sexology' experts and later psychoanalysts contested religious doctrines on reproduction and sexual behavior and argued against the criminalization of same sex relations, the new science of sex also crafted the powerful concept of a universal human sexual instinct that glossed over the wide variability of cultural meanings in respect to sexuality, gender, and reproduction, placed reproductive behavior at the top of a taxonomic hierarchy of sexual practices, and overlapped with racial and class views associated with eugenics (Rubin, 1984).

Paradoxically, these political and scientific ideas on 'sex,' gender, and reproduction both inspired many emancipatory projects, such as those propelled by feminist pioneers' and progressives' fight for birth control and sexual reforms, and fed a vast arsenal of ideas of social control, discipline, hierarchizing, and marginalization. And they continue to influence political debates, policy propositions, and controversies around the regulation of fertility. The paradox is illustrated in the biography of Margaret Sanger, the early twentieth-century North American radical advocate of contraception and abortion. From the late 1920s, Sanger established connections with neo-Malthusian and eugenic groups and created the International Birth Control League, later renamed the International Planned Parenthood Federation (IPPF). This institution worked with colonial administrations and propelled the emergence of local birth control associations in the Southern hemisphere, which would play a major role in the fertility control initiatives of the 1960s (Chesler, 1992).

The biopolitical tragedy of Nazi-Fascism imposed silence on the most radical and salient pre-World War II eugenic proposals. But ideas and policy proposals around birth control did not die away and by the 1950s linked up with a new wave of population concerns now crafted in planetary terms and articulated with economic development theory: excessive or too rapid population growth would impair state economies. By then Sanger was a sponsor of research leading to the invention of the pill, which would become the icon of women's sexual and reproductive autonomy – even of sexual liberation more broadly speaking. Yet the pill would also become a key element in the post-World War II transnational machinery of population control.

In the 1960s, geopolitical tensions of the Cold War were at their height when a youth Cultural Revolution flared across industrialized societies, provoking as well eruptions in the socialist world and Latin America. The 1960s sexual rebellion inaugurated the politics of gender, sexuality, and reproduction, as we know it today. It preceded the 1970s and 1980s legal reforms in the realms of gender equality, abortion, and contraception and also the decriminalization of sex relations (mostly but not exclusively in affluent societies). It also inspired the contemporary wave of sexuality theorizing that challenged the normalizing and colonizing effects of positivist and naturalist tenets of nineteenth-century sex science (Correa et al., 2013).

But, in 1968, a book titled *The Population Bomb* (Ehrlich and Ehrlich, 1968) was also published. Its Cold War rhetoric about high fertility rates in the regions south of the equator fueled concern about mass starvation and societal upheavals. Although not all actors engaged in population research and related debates called for coercive measures of fertility control, the debate took flagrant colonial, racist and, quite often, eugenic turns (Hartmann, 1995).

At the first UN Conference on Population, in Bucharest in 1974, Third World countries reacted to population control rationales by crafting the proposition: "Development is the best contraceptive." However, in many cases this rhetoric simply concealed deeply rooted pronatalist stances. Yet not all developing nations remained faithful to their Bucharest commitment. By the late 1970s, draconian population control was already in place in Asia, particularly in China, and India and Mexico had also adopted a national policy based on fertility targets.

From the late 1970s, these politically intricate paradoxes began to be critically deconstructed through debates around gender equality, reproductive autonomy, and sexual freedom transnationally and in a series of United Nations processes and conferences. As early as the late 1960s feminists

had begun to criticize international population policies, fertility targets, and coercive contraceptive provisions. Feminist groups that began blossoming South of the Equator most often supported the 1974 Bucharest 'Third World development agenda' but they also criticized population control's negative effects on women's health, lives, and autonomy as well as the pronatalist views of their governments and of religious institutions. In the case of Latin America feminist critiques targeted in particular the Catholic Church that viewed women as reproducers and called for quality contraception and legal abortion. They also addressed the racialized biases of fertility control globally and within countries – as exemplified by South African apartheid population policies – and raised sharp critiques in respect to the bad quality of care provided by both mother and child programs, which dominated states' responses to women's health needs all across the global South (Corrêa and Reichmann, 1994).

Later in 1984 in Amsterdam, the first International Reproductive Rights Conference sponsored by the International Campaign on Abortion, Sterilization and Contraception gathered feminists from all over the world. On this occasion the Women's Global Network on Reproductive Rights (WGNRR) was created and a transnational consensus was reached around the concept of reproductive rights defined as "women's right to decide whether, when and how to have children – regardless of nationality, class, race, age, religion, disability, sexuality or marital status – in the social, economic and political conditions that make such decisions possible." One key feature of this consensus entailed the broadening of reproductive autonomy tenets beyond abortion, contraception, and sterilization, to include maternal mortality, prenatal and obstetric care, breast and cervical cancer, and adolescent and postmenopausal health. Southern feminists also strongly emphasized that women's labor rights and social reproduction roles should be part of the reproductive rights agenda (Dixon-Mueller, 1993).

The subsequent WGNRR-sponsored Women's Health Conference held in San Jose, Costa Rica (1987), began an international campaign to fight maternal mortality and inspired the creation of the Latin American Campaign for the Decriminalization of Abortion. In Manila, in 1990, at the next Women's Health Conference, the proposal was made that the international reproductive rights movement should dare to conceptualize a feminist population policy.

These debates and processes must also be situated in relation to the HIV/AIDS epidemics. Recognized in the early 1980s in the West among primarily gay men and later as a generalized global epidemic, the epidemic brought with it a human tragedy of gigantic proportions and propelled establishment of new global policy frames that would have impact on national sexual and reproductive laws and policies. AIDS has also, and paradoxically, opened key inroads for public and political discourses on sexuality-related discrimination and stigma to blossom worldwide (Altman, 2013; Parker, 2001).

The United Nations Policy Arenas

The first UN International Conference on Human Rights held in Tehran in 1968 approved a principle ensuring couples the "basic human right to decide freely and responsibly on the number and spacing of their children and a right to adequate education and information in this respect." In 1974 in Bucharest, despite the geopolitical tensions and skirmishes, this definition was rephrased to extend these rights to individuals (not just couples) and to ensure access to the means of exercising them.

Concurrently gender equality concerns in relation to dominant family planning frameworks were evolving. In 1975, in the First United Nations sponsored International Women's Conference held in Mexico City, coercive measures of population control were openly criticized and the final document claimed respect for the bodily integrity of women as 'a fundamental element of human dignity and freedom.' In 1979, the Convention on the Elimination of All Forms of Violence against Women (CEDAW) affirmed women's rights to family planning, equal right (with men) to decide on the number and spacing of children, the right to maintain their jobs while pregnant, and to have access to maternity leave and childcare. In 1981, an UN Symposium on Population and Human Rights held in Vienna also declared that "Both the compulsory use of abortion and its unqualified prohibition would be a serious violation of human rights."

Despite this emerging consensus, the global policy climate in relation to reproductive autonomy was far from favorable. At the International Population Conference of Mexico in 1984, while developing countries expressed a broader acceptance of women's right of access to contraception, an alliance between the United States' Reagan Administration and the Vatican openly targeted family planning programs, particularly abortion; the United States announced that it would suspend funding for these programs, including to the United Nation Population Fund (UNFPA), a policy that would remain in place until 1993. On the other hand, by the end of the 1980s, the World Health Organization framed and adopted the notions of reproductive and sexual health that would later be incorporated by other UN institutions as well as by feminist and HIV/AIDS activists (Dixon-Mueller, 1993).

Then in the 1990s, in the Cairo and Beijing Conferences, UN member states agreed upon the definitions of reproductive rights and of sexual rights of women. These groundbreaking agreements were the result of debates that took place in a series of conferences sponsored by the United Nations in the 1990s: Environment and Development (Rio 1992), Human Rights (Vienna 1993), Population and Development (Cairo 1994), Social Development (Copenhagen 1995), and finally Women (Beijing, 1995). For example, the 1993 Vienna Conference legitimized the premises of women's rights in public and private spheres – regardless of cultural relativity – and established the indivisibility of civil, political, economic, and social rights, both definitions being crucial for the further the development of reproductive and sexual rights.

Whereas in the 1970 and 1980s, both Northern and Southern feminist intellectual and political endeavors had evolved largely disconnected from international policy arenas, in the 1990s, feminists were directly engaged in these UN negotiations and the presence and impact of global South feminist perspectives were palpable. The Cairo Conference and its reaffirmation and expansion in Beijing were correctly interpreted as a major paradigm shift from long-standing instrumental population concerns toward a perspective based

on gender equality, human rights, and health. On the other hand these negotiations were contentious. Although many countries from the economic South – mostly from Latin America, but also South Africa, India, and even Egypt – moved toward supporting gender equality, reproductive rights, and even sexual rights, the conservative resistance was fierce and systematic. Initially clustered around the Vatican and its allied Latin American and African countries, this hub of resistance expanded to include Islamic states and also some Asian and African countries.

Although this systematic opposition – named by feminists as the Unholy Alliance – was not able to block the political consensus in the agreed documents, it was the origin of a consistent platform of resistance to the application of human rights to sexuality and reproduction that continues to operate in all UN global policy arenas. The tensions at play in these early 1990s UN disputes were hotter than similar controversies then underway at national levels, with the exception of the United States. These difficult UN negotiations anticipated the harsh political climate that, in the 2000s, also prevails at national levels, across continents, in relation to reproductive and sexual rights claims (Sen and Corrêa, 1999).

The 2000s Policy and Political Landscape

The first decade and a half of the twenty-first century has seen the expansion and greater visibility of rights claims in the domain of reproductive and sexual rights, and a diversification of voices, subjects, and demands (Ilkkaracan and Jolly, 2007). Political mobilizing for abortion rights mushroomed in almost all countries, while the women's reproductive and sexual agenda continued to address issues of contraception and expanded to encompass HIV/AIDS prevention and treatment, radically transforming the global map of reproductive politics (Harcourt, 2009). Arguably the 2000s have also been the era of sexual rights broadly speaking, as claims of equality, nondiscrimination and protection from violence of persons whose sexual orientation and gender identity differ from the dominant norms have blossomed nationally and globally, as incalculable choreographies of sexual and gender diversity and malleability have erupted, so to speak, in terms of political and media visibility (Richardson, 2000; Thoresen, 2009). Concurrently the political demands of sex workers have also become more palpable and transnationally connected (Kempadoo and Doezema, 1998).

These dynamics are decidedly linked to enormous changes in communication technologies allowing for ideas and practices to cross state boundaries, to the deep and wide impacts of market forces in terms of recreating sexual cultures and reproductive practices, and to intensified migration (Altman, 2002; Parker, 1999; Tan, 2014). However, mobilization and advocacy at both local and global levels around reproductive and sexual rights since the 1990s and the cultural and normative changes resulting from these efforts are also key factors. Since 1995 UN language and norms spread across many policy levels and propelled the imagination of those whose rights are violated in the most diverse settings. Even though these definitions were not legally binding, they have become ethical and normative parameters on the basis of which existing laws and norms even within private institutions, such as biomedical procedures, could be contested and their detrimental effects rejected.

For example, in 1994, the UN Committee on Human Rights in the case of *Toonen v. Australia* concluded that Toonen's right to privacy was violated by the sodomy law remaining in the books of the state of Tasmania, and called Australia to review the legislation. In 2003, Brazil tabled the first resolution presented to the UN explicitly addressing sexual orientation and human rights at the UN Human Rights Commission. Although the Brazilian initiative faced great resistance from Islamic states and was not successful, it propelled a sustained global political mobilization around the rights of sexually nonconforming persons in the context of UN policy arenas, in particular the UN Human Rights Council (HRC) established in 2005 (Girard, 2007).

Then, in 2006, an independent international group of experts and activists elaborated the Yogyakarta Principles for the Application of Human Rights in relation to Sexual Orientation and Gender Identity. This document anchored the human rights claims related to sexual orientation and gender identity in consecrated premises of international law, and became an intellectual inspiration, both globally and nationally, for activists as well as jurists, legislators, and policy makers (O′ Flaherty and Fisher, 2008). Since 2008 a series of declarations and one resolution on sexual orientation, gender identity, and human rights have been presented and adopted by the UN HRC and there are strong indications that in the next few years substantial resolutions on human rights applied to sexual orientation and gender identity will be adopted and permanent mechanisms for monitoring these rights will be established. In parallel, since 1994 numerous sexual orientation and gender identity cases have been examined with positive results by UN human rights bodies as well as by the European and Inter-American judicial systems (Saiz, 2004; International Commission of Jurists, 2010).

These international debates were surrounded by national debates and law reforms in relation to LGBTQI rights in a wide range of countries. While legal reforms regarding same sex civil union and marriage equality tend to capture greater media and public attention, groundbreaking antidiscrimination legislation and specific laws concerning gender identity have also materialized in recent years in diverse settings (Currah et al., 2006). Not less importantly, political struggles, legal suits, and legislative debates against the criminalization of same sex relations have also multiplied in the most diverse settings.

Legal gains in this domain achieved since the 1990s have not been confined to so-called affluent nations. New constitutions in Ecuador, South Africa, and Fiji in the 1990s included sexual orientation in their prohibition of discrimination; in 2008 Nepal's Supreme Court declared full fundamental human rights for 'sexual and gender minorities.' Criminal laws prohibiting sodomy were declared unconstitutional not only in the United States (2003) but also in Nicaragua (2008), Panama (2008), and the groundbreaking Delhi High Court decision on article 377 of the Indian Penal Code in July 2009, which would be,

however, struck down by the Indian Supreme Court on December 2013 (Boyce and Khanna, 2011; Tamale, 2009). In 2012, a new Argentinean law on gender identity broke ground by not requiring a psychiatric diagnosis before obtaining a new social identity and body modification procedures (Cabral, 2012).

Reforms in relation to same sex unions or marriage either through legislation or court decisions have also not been limited to the global North. The list includes various U.S. states, European countries, such as France, Spain, and Portugal, and New Zealand. But reforms have also been approved in Argentina, Brazil, Colombia, Mexico, South Africa, and Uruguay, and there are indications that they may soon take place in Vietnam and Thailand. The extension of marriage equality to same sex couples is a relevant development regarding sexual rights, but it also has important reproductive rights implications.

Turning specifically to the politics of reproduction, beginning in the early 2000s, reproductive rights cases began to be more systematically examined in international and regional human rights systems. In 2003, the UN Human Rights Committee in the *KL v. Peru* case condemned Peru for not providing abortion when the young woman was carrying a baby with grave fetal abnormality. In 2005, in the *Paulina v. Mexico* case scrutinized by the Inter-American Human Rights Commission, Mexico was condemned for not providing access to abortion when the woman had been raped and the state law permitted abortion in this case. In 2011, the CEDAW committee examining a maternal mortality case – the *Alyne Pimentel Case* – condemned Brazil for having infringed the fundamental rights of Alyne as defined by the Convention (Garita et al., forthcoming).

A major breakthrough was the adoption in November 2005 of the African Protocol on Women's Rights known as the Maputo Protocol. According to the Center for Reproductive Rights it is the first legally binding human rights instrument to fully articulate women's reproductive rights as human rights, and to expressly guarantee a woman's right to control her fertility, affirming women's right to reproductive choice and autonomy. The Protocol is critical not only for Africa but it also sets a parameter for struggles and claims elsewhere. Then in 2008 a resolution adopted by the Human Rights Council for the first time defined maternal mortality as a human rights violation. Although the text does not explicitly mention abortion, it called for the Office of the High Commissioner of Human Rights to study these violations. The resulting report made public in 2012 identifies illegal and unsafe abortion as one main cause of maternal mortality as a human rights violation (Center for Reproductive Rights, 2006).

Since 1995, 16 countries have reduced legal barriers to abortion, most principally on the basis of health reasons, but in some cases law reforms have also included rape, economic necessity, and fetal malformation as justified reasons for the termination of pregnancy. Most of these countries are in Africa: Benin (2003), Burkina Faso (2003), Chad (2002), Ethiopia (2004), Guinea (2000), Mali (2000), Saint Lucia (2004), Swaziland (2005), and Togo (2007). The list also includes Saint Lucia (2004), Bhutan (2003), and the 2006 groundbreaking decisions of the Colombian Constitutional Court, considered by some analysts as a full fledge abortion reform. Most significantly, in nine countries recent reforms occurred that made abortion legally available without restriction within the first 12–14 weeks of pregnancy: Albania (1996), Ethiopia (2005), Cambodia (1997), Nepal (2002), Portugal (2007), Spain (2010), South Africa (1996), Switzerland (2002), and Uruguay (2012); and state-level reforms have also taken place in Australia (2007) and in the Federal District of Mexico (April 2007). As the list shows, the large majority of progressive abortion reforms have taken place in the global South where legislation was previously more restrictive (Center for Reproductive Rights, 2013).

What were the conditions that enabled these recent developments? Since the 1990s, the poorly understood and poorly regulated forces of globalization had been sweeping the world. These forces deeply altered cultures by favoring the transformation of sexual and gender orders, women's labor patterns, and household structures in ways that potentially favored sexual and reproductive autonomy and greater moral pluralism in societies (Petchesky and Judd, 1998). They also propelled across continents the absorption and use of the lingua franca of human rights, including in relation to matters related to sexuality and reproduction (Cheah, 1997; Pecheny and de la Dehesa, 2014). On the other hand, global transformations propel novel and more complex patterns of social and economic inequalities, within and across countries, and immense financial instability across boundaries and geoeconomic shifts. For example, the 2008 financial crisis in the United States and Europe had devastating effects on employment, inequality, and poverty and led to the repositioning of former peripheral big economies – Brazil, Russia, India, China, and South Africa as the new emerging global players. The realization of reproductive and sexual rights is necessarily affected by worsening inequalities and their future developments will have to be mapped and understood in relation to these global shifts.

Furthermore globalization, as it is widely known, went hand in hand with neoliberal policy frameworks based on market-oriented policy models, including the continuing privatization of health systems, either through public–private partnerships, or in more extreme forms. The existence of functional, accessible, and affordable or free health services is a key enabling condition for the exercise of reproductive rights. Decriminalizing abortion is not sufficient; safe abortions require the support of health services. Similarly, access to quality care health services constitutes an important element of the enabling conditions for sexual rights, including HIV/AIDS prevention and care, and the medical needs of trans- and intersex persons.

Yet, since the 1990s, partial or total privatization of health care has increased worldwide, including in Europe where welfare states are being dismantled by stringent austerity fiscal measures; or even in Brazil where the system established in the 1980s was premised on principles of universal coverage and gratuity. The 2011 U.S. health care reform may appear exceptional, but it was designed to ease the sharp detrimental effects of extreme privatization that prevailed in the American system since the 1980s. In any case, if the ICPD policy agenda was premised, to a large extent, on the existence of publicly funded, universal and free of charge health systems, this aspiration has not materialized South or North of the Equator.

In 2010 a group of feminist researchers and activists organized a meeting in Lankawi, Malaysia, to critically charter key

factors negatively impacting on the implementation of the reproductive health and rights agenda that had emerged from the 1990s UN cycle of conferences. They concluded that "Inequities in access to health care due to the increasing privatization and commodification of health services and health insurance, the introduction of internal markets into health care delivery, and decades-old policies of charging user fees in the public health system on top of out-of-pocket costs, have undermined the myriad commitments made by governments and other institutions of power to achieving health for all, including sexual and reproductive health." (Berer, 2011, page 3).

Furthermore, despite positive developments since the 1990s in terms of international norms, national legal reforms, and wide cultural transformations, reproductive and sexual rights have been and continue to be fiercely resisted. Some states – such as China, India, Indonesia, and Vietnam – had been implementing for decades top-down and coercive population policies that would not be easily transformed. In some of these cases, governments, despite having signed the agreement, had no real interest in implementing the required changes; in others, obstacles to transforming policies were not easily overcome.

In China, for example, the strict one child policy remained in place until recently when demographic and economic reasons justified its flexibilization. Quality of care in reproductive care gained space in official policy discourses, but the widespread practice of coercive abortion and contraception was not eliminated. In India, under the pressure of women's organizations, new reproductive health guidelines based on the ICPD premises were adopted by the central government, but reframing the fertility control machinery proved to be daunting. Another example is Vietnam where the early openness to the Cairo agenda would be left behind by the 2000s when the government became anxious about the results of the new market-oriented economic policy then being implemented.

In summary, either because population control models are too resilient or because the ambitious rights agendas of ICPD and Beijing were not absorbed uniformly across the world, almost 20 years later problems related to coercive fertility control practices have not disappeared. A number of recent press reports and academic research findings made visible episodes of female sterilization abuse in contexts as varied as in India, where women are still dying after sterilization camps' procedure, and Slovakia, where Roma women were submitted to forceful tubal ligations; or the 2012 scandal of forced female sterilization scandal in Uzbeskisthan that reached the front pages of the global press.

The refractory policy structures of population control are not the only or even major challenge. Another major obstacle is what the French philosopher Jacques Derrida called 'the return of religion' (Derrida, 1998). Contemporary religious dogmatic revivals that began to be visible in the 1970s have gained scalar proportions in the past 20 years. Today dogmatic visions are manifest in all dominant religious traditions and, practically everywhere, politically organized religious extremists operate to influence legal norms and policies, or take state power through electoral politics. Some authors have interpreted these extremist revivals as a reaction to the growing uncertainties of late capitalism. They pose unpredicted challenges with respect to the foundations and meanings of secularity and everywhere they target transformations underway in sexual, gender, and reproductive orders as one main strategy to recreate 'tradition' and enlarge the space for dominant heteronormativity and sexism to regain social and political legitimacy (Corrêa et al., 2008).

These forces have impacted on the Cairo and Beijing rights agenda and related processes in many ways. For example, following George W. Bush's election in 2000, his administration reinstated Reagan's Global Gag Rule, prohibiting overseas recipients of United States Agency for International Development (USAID) funds to research, provide, or advocate for. Later in 2003 the President's Emergency Plan for AIDS Relief (PEPFAR) was enshrined into a law and began globally promoting abstinence and monogamy as prevention. One year later Congress approved the Trafficking Victims Protection Reauthorization Act (TVPRA) that prohibits organizations receiving U.S. funds to recognize and advocate for the rights of sex workers.

Although since 2009 the Obama administration has either suspended or eased these directives, the effects of the Bush era American policy are still felt in many Southern countries. Furthermore, in the past 20 years U.S. conservative religious forces and advocates have begun to export their agendas worldwide.

The presence of U.S. Evangelicals in sub-Saharan Africa has been triggering trails of sexual panic, violence, murder, and incarceration of gays, lesbians, and trans persons, but also the proposal of extremely regressive legislation in respect to both homosexuality and abortion (Kaoma, 2012). U.S. extremist Evangelism has also established connections with groups in Latin American countries, such as Brazil, where the number of Evangelicals has significantly increased, as well as in China. The rise of active antiabortion forces in the United Kingdom also articulates with similar U.S. initiatives, at least tactically, such as rescue operations in front of clinics.

Religious dogmatic attacks on reproductive and sexual rights in the United States and elsewhere, while strongly grounded in Biblical Evangelism, are also promoted by the Catholic leadership, intellectuals, and groups of faithful. Catholic conservative voices are active in Ireland, the Philippines, Poland, Portugal, Spain, a number of African countries, all of Latin America, and even France, a country known for its strong attachment to secularism and laicité. Mobilizing civil society and media, they sometimes work to elect antiabortion and antihomosexuality politicians to directly influence legislative and judiciary bodies. In contrast to other dogmatic religious voices, contemporary conservative Catholic arguments and strategies are no longer exclusively grounded on faith and theological morality. Rather they are framed in terms of natural law premises and revised forms of constitutionalism and, most significantly, they also resort to bioscientific arguments – in relation to the beginning of life or binary conception of sex and gender to construct political arguments against abortion and homosexuality (Lemaitre, 2012).

When the lens is shifted toward the Islamic world we see the caveats of Islamic cultural and legal norms in respect to gender and sexuality. Yet Islamic doctrine with respect to abortion and contraception has sometimes proved more flexible than Christian extremist canons. Abortion has long been legal in

Turkey (1980s) and Tunisia (1970s), and Iran had until recently a national family planning program and allowed abortion for health reasons.

But once again, since Cairo and Beijing, Islamic states and leaders have also moved toward more radically regressive positions in relation to gender, sexuality, and reproductive matters. In many contexts in Africa, the Middle East, and Asia, Islamic extremists quite often revive the historical racist bias of population control policies to portray and condemn contraception as another Western strategy to reduce the number of Muslims. In 2012 the Turkish president took feminist groups by surprise when he declared the right to abortion should be abolished. In the aftermath of the Arab Spring, new threats to gender equality and related claims in the realms of sexual and reproductive autonomy are also taking place in Egypt and Tunisia after Islamist parties gained election. Positions against reproductive autonomy can also be identified in other non-Christian religious cultures as exemplified by Sri Lankan conservative Buddhists' public positions against abortion. Current debates around sex-selective abortions in India and China – which are blatant examples of violation of women's equality – are now interwoven with slippery discourses on female feticide and the right of girls to be born that easily feed antiabortion stances.

These cross-boundary and multilayered regressive politics have had detrimental effects worldwide. In the heated debates around the 2011 U.S. health reform public funding for abortion procedures was limited. In 2010, in Kenya, religious dogmatic pressures led to the inclusion of a right to life from conception in the text of the new constitution. In the Philippines, a new reproductive health law was voted by the House in 2012 – after many years of feminist struggle – which was once again heavily attacked by the Catholic Church. As of early 2014 final approval of the law was still pending. In Portugal and Spain, Catholic conservatives who systematically attacked recent abortion legal reforms have gained the support of conservative governments elected after 2011.

In Latin America and the Caribbean, Nicaragua (2008) and Dominican Republic (2011), abortion has been totally banned as in Chile (adding to the list of the extremely restrictive laws of El Salvador and Honduras). Strong Catholic pressures delayed the approval of the Uruguayan abortion law for 8 years. In Colombia the 2007 decision of the Constitutional Court allowing access to safe and legal abortion to preserve women's health is resisted at the level of health services. In Mexico, after legal abortion was granted in the Federal District, a number of states adopted a right to life premise in their constitutions. In Brazil, the alliance between conservative Catholics and Evangelicals has been propelling flagrant policy regressions, such as the 2010 law provision to guarantee personhood status to the unborn. Everywhere, South and North of the Equator, conscientious objection is being diffused creating obstacles to access abortion in contexts where it is partially or totally legal.

The impacts of the 'return of religion' are also identified in global policy arenas, in particular United Nations bodies and forums. Since the early 2000s, when the Bush administration strongly pressured for and succeeded in deleting ICPD reproductive health targets and indicators from the Millennium Development Agenda (the targets would be restored in 2005), UN agencies and others have gradually tended to fall back toward a more conventional maternal health and maternal morality, far from sufficient from the point of view of a comprehensive reproductive (and sexual) rights perspective. Furthermore, the Vatican, some Catholic states, and Islamic countries organized around the Organization of the Islamic Conference, and many faith-based religious organizations are now much more present in negotiations involving women's rights, particularly sexual and reproductive rights, than in the 1990s.

In each new UN debate on these topics, a renewed battle erupts making it more and more difficult to preserve the premises of these rights as defined in the 1990s intergovernmental consensus. Despite gains such as the *KL v. Peru* and *Paulina v. Mexico* cases, great difficulties are now experienced with respect to language on abortion rights. For example, it was impossible to explicitly include abortion as a main cause of maternal mortality in the resolutions adopted by the Human Rights Council in 2008.

Alice Miller and Mindy Roseman in a recent assessment of key challenges in sexual and reproductive rights work correctly observe that though both LGBTQI rights and abortion rights are under fierce attack in all UN negotiations and processes in terms of normative developments a flagrant asymmetry is observed. During the past 10 years important forward steps have occurred in respect to granting rights related to sexual orientation and gender identity on the grounds of equality, non-discrimination, right to privacy, and autonomy. In contrast, 20 years after Cairo and Beijing, no international human rights surveillance committee nor UN high-level expert – except the Special Rapporteur on the Right to the Highest Standard of Health – had dared to frontally addressed the decriminalization of abortion on the same grounds or even as a core component of the right to health (United Nations, 2012).

The development of sexual and reproductive rights must also be situated in relation to major developments underway in the vast domain of biomedicine and biotechnology. This dimension had always a central place in earlier debates on population control and sexual and reproductive health and rights, as exemplified by long-standing discussions on contraception and abortion technologies, including those related to sex-selective abortion and HIV/AIDS prevention and treatment, to mention a few. However, the magnitude of scientific and technological breakthroughs of the past 30 years is of a new scale.

These transformations are at the background of the revival of conceptual and policy frames that increasingly privilege technological means as the easiest and quickest solution to complex social problems over the long-term and more uncertain processes of political and cultural transformation. This tendency that, in the 1980s and 1990s debates on population, was criticized by feminists as simplistic tech fix solutions is once again blossoming in diverse areas related to sexual and reproductive health and rights. One example is the recent development of new medical technologies of HIV prevention – such as pre- and postexposure prophylaxis and male circumcision. These new strategies of prevention tend to be disseminated through vertical delivery programs, very similar to those adopted by past fertility control programs, that have incurred in many distortions, such as uncontrolled

side effects and lack of attention to cultural dimensions. Most compelling perhaps is the 'new' global initiative on family planning, launched in 2012 that is supported by the Gates Foundation and DFID and focuses mainly in sub-Saharan Africa. While portrayed by the global mainstream media as a policy proposition that challenges religious views on contraception, the initiative dismisses the Cairo and Beijing comprehensive rights approach and, not surprisingly, has been criticized by many reproductive rights research and advocacy voices from both North and South of the Equator.

Recent scientific and technological developments in the biomedical field are deeply imbricated with neoliberal mechanisms of governamentality that devolve and disperse regulatory functions from the state toward self-regulatory mechanisms of private institutions or consumers. Under these rapidly shifting conditions, the further development, elaboration, diffusion, and political mobilization around reproductive and sexual rights claims are becoming exceedingly more complex, fragmented, and contradictory. Individuals, specific social groups and societies at large, in all continents are both absorbing and negatively reacting to the intense medicalization of practices and the aggressive commercialization of pharmaceutical and biotech products and services, in a world that remains traversed by sharp national and global economic inequities.

On the one hand, millions of people around the world are still coping with 'old' biomedical and technological issues such as the limited options for and poor quality of contraception, restrictions in the access to medical abortion technologies, the high costs of ARVs and the basic obstacles experienced by trans persons in accessing safe body modification and sex reassignment procedures. At the same time the transnationalization of new reproductive technologies including surrogacy or the skyrocketing global marketing for sexual enhancers such as Viagra is now commonplace, not to mention a wide range of novel techniques of body modification including sophisticated plastic surgery of genitals. These are the paradoxical frontlines of what Nikolas Rose – is his chartering of contemporary trends in medicalization, biotechnology, and bio-capitalism – defines as biological citizenship struggles (Rose, 2006).

Political and Conceptual Inquiries

Reproduction, Sexuality and Human Rights: Intersections and Distinctions

Both in theory and in practice, reproductive and sexual right both intersect and are distinct in a variety of complex ways, in the same manner sexuality and gender can overlap or diverge as domains of personal and social relations. It might be useful for reproductive rights advocates to consider how diverse sexualities and reproduction can be both intertwined and delinked and to recognize that sexual and gender diversities raise new challenges for reproductive locations, aspirations, and politics.

Likewise, sexual rights advocates might begin to examine the reproductive potentials of nonnormative sexual and gender identities at the same time they continue to explore the transgressive (as well as accommodative) potentials of every variation in the sex–gender rainbow. They would also do well to recognize that the reproductive realm is not exempt from transgressive practices, the most evident example being the widespread recourse to abortion in contexts where it is criminalized.

These analytical efforts may be guided by confronting such issues as sexual hierarchies; sexual pleasure as a right of heterosexuals and sexual dissidents alike; reproductive and sexual health services that go beyond the dominant gender binary that prevails in biomedical interventions; condemnation of forced sterilization of not only women, men, and disabled persons but also trans persons; reproductive rights as a frame not only for the right of infertile women to become pregnant, but also for the choice of lesbians to be pregnant and to bear and raise children and the complex situations in which single men or gay couples resort to surrogate mothers to be able to biologically reproduce; rights of gay men, trans and intersex people, and sex workers to adopt and raise children; family-related benefits within nontraditional households and kin networks, for persons rather than couples.

Engaging such questions should move us toward greater inclusivity in how we conceptualize both reproductive and erotic justice.

The Indispensability and Insufficiency of Rights

An enabling environment – democratic conditions, social and economic well-being, gender equality, and a climate of ethical pluralism – is a prerequisite for the realization and full exercise of reproductive and by extension sexual rights. Reproductive and sexual rights claims imply both positive entitlements – such as reproductive health care, employment, social security support – and negative rights, such as protection against rape and discrimination, regardless of gender, race ethnicity, or sexual orientation or gender identity and expression. There are no significant signs that these prerequisites have been fulfilled or even significantly improved in the past decade.

However, it is also evident that everywhere, including in the global South, gays, lesbian, and even trans persons who have access to economic, knowledge, and symbolic resources may live their lives without experiencing high levels of discrimination or violence; and affluent women can access safe abortion procedures even where it is illegal. The skyrocketing expansion of LGBT tourist routes and of medical tourism in the area of sexual and reproductive health-specialized services (such as insemination, IFV, surrogacy, and body modifications) is other striking examples of how persons with access to resources may be sexually and reproductively entitled. Yet millions who also have needs and aspirations in the realms of reproduction and sexuality suffer inequalities, lack of resources, threats to personal safety, and human rights violations. The requisite of enabling conditions is therefore, perhaps, more urgent today than in the past.

The trajectory of the past two decades reveals that addressing reproductive and sexuality claims through the liberal paradigm of inclusion through citizenship and human rights had unequivocal gains. Human rights language and interpretative work have been decidedly engendered and sexualized and there have been achievements in relation to nondiscrimination, equality under the law, right to privacy, self-determination, and freedom of expression. This is critical because the realization of reproductive and sexual rights

cannot be attained if premises of personal and individual agency are not guaranteed. However, the androcentric, individualistic, and contractual nature of the dominant Western liberal theory and practice of rights must also be challenged.

World realities make it more compelling today to continue developing reproductive and sexual rights as social and collective entitlements. Furthermore the conversation around these rights must also be situated in relation to militarization and securitization trends in many places. The 'states of exception' that prevail in these circumstances and sites turn rights language and claims into meaningless resources.

With the justice framework proposed by Nancy Fraser (1997) in mind, articulating principles of recognition and redistribution, how can we soberly assess, for example, recent legal victories in relation to same sex marriage in those settings that remain fraught by sharp economic inequalities, where poor trans persons are targets of homophobic murder and no prospect exists for poor women to have access to safe and legal abortion in the short term? We need to critically examine the many pitfalls of the Indian surrogacy industry after access to these services for foreign single individuals and same-sex couples was prohibited in 2013 both from the point of view of poor women who rent their wombs to sustain their family livelihoods and that of those persons who may be said to have been discriminated against by the new rules. What can we say about the total absence of sexual and reproductive entitlements of millions of persons incarcerated worldwide (particularly in the United States, Brazil, and China that comprise almost 80% of the global inmate population), or of refugees from conflicts in Syria and elsewhere?

To once again return to Jacques Derrida, rights work in relation to reproduction and sexuality cannot avoid threading the thin line between, on the one hand, the appraisal and enlargement of rights language as indispensable and, on the other, the recognition that rights are also insufficient to meet expanded demands of justice (Derrida, 1992).

Religious Dogmatism, Secularity, and Science: Troubled Crossroads

As increasingly extremist forms of religion directly attack gender equality and reproductive and sexual freedoms, secularity and *laicité* has gradually gained an aura of either a lost golden age, or a key pathway to overcome the threats of dogmatism. We must be cautious with this schematic division locating religion on the side of gender domination and sexual repression and secularity as the realm of gender equality and sexual freedom and nondiscrimination. The historical experience and current realities are much more complex and hazy. Even in a number of countries hailed for respect for secularity, the separation between state and church were not are as sharp and clear as suggested. Both in the past and today secular states institutions and norms have curtailed and continue to curtail reproductive and sexual autonomy, either because they remained influenced by religious views, or because they are informed by strictly secular, in fact, scientific rationales of control and discipline. The criminalization of abortion may be impregnated with religious morality, but it has well-served states' natalist objectives. Sodomy laws were much more about the secular morality of the male bourgeois and colonizer and scientific notions of sexual deviance than about sin. The sexual ideologies of communist states where secularity was compulsory were not exactly liberal.

Secularity and secularization are without doubt enabling conditions or prerequisites of religious freedom as well as of moral plurality required for the realization of gender, reproductive, and erotic justice. But secularity should neither be mystified as a silver bullet that will resolve the conflicts and controversies of sexual and reproductive politics today, nor spared from critical assessments. Quite possibly for the foreseeable future reproductive and sexual rights activists and intellectuals will be challenged to reengage with religion without 'returning' there. This implies recognizing religion as a perennial, perhaps, but also changing aspect of political and social reality, not it's 'opposite.' This kind of critical engagement with religions means contesting the injustices perpetrated in their names, while avoiding the demonization of religious communities as a whole – as occurs in the case of Islamophobia – while at the same time opening spaces and establishing connection with the voices of plurality and respect to sexual and reproductive freedom that exist in all religious traditions.

Caution is also required in respect to science (and technology) as the main strategic intellectual and pragmatic resource to countervail religious dogmatism. The core tenets of scientific inquiry and the valuing of systematic doubt and empirical evidence are certainly important sources to guide arguments in favor of reproductive and erotic justice in the difficult and complex conversations underway in the most diverse public spheres torn apart today between religious and nonreligious visions on these matters. However we must remember that dominant scientific conceptions of 'sex,' gender, and reproduction also place these dimensions of human experience squarely in the laws of nature hampering transformed visions that emphasize the contingency and plasticity of these domains, which are critical to the contemporary politics of reproduction and sexuality. The naturalizing imprint of scientific conceptions and discourses is what allows them to be increasingly used by dogmatic religious actors in their political arguments around the right to life or unshakable natural imprint of gender, sexual attraction, and love.

Lastly but not less relevant scientific rationales have been and remain one key source of ideologies of social engineering – and within it of extreme forms of sexual and reproductive disciplining or even triage. The ethical risks and potential human rights violations implied by the uses and abuses of scientific instrumental rationality for societal administration are greater and more palpable today than ever. The future development of sexual and reproductive rights is therefore challenged to increasingly engage with the novel trends and scientific production as to make sure that science and technology will be guided by the ethical premises of freedom of will, expression and consciousness, equality, privacy, and nondiscrimination.

Reproductive Rights in Affluent Nations

Abstract

Reproductive rights have historically focused on access to safe, legal contraception and abortion. More recently, reproductive rights have come to include preservation of reproductive health and access to assisted reproductive and genetic technologies that facilitate procreation. Recognition of additional barriers to reproductive self-determination experienced by members of marginalized groups has led to demands for reproductive justice that address the concerns of poor women, racialized women, women with disabilities, and LGBTQ individuals.

Introduction

Beginning in the nineteenth century and gaining strength in the twentieth century, the struggles for access to safe, legal contraception and abortion have been the most dominant issues in the pursuit of reproductive rights in developed nations. Recent advances in technology have meant that assisted reproduction and genetic screening and testing have also become contested sites in struggles over reproductive rights. Earlier accounts of reproductive rights were largely concerned with women's abilities to make choices to avoid unwanted procreation, whereas in the contemporary context, reproductive rights have been argued to include a spectrum of rights aimed at preserving women's reproductive health, enabling procreation, and possibly determining the characteristics of one's future children. Whereas earlier struggles over contraception and abortion were framed as upholding women's reproductive autonomy, recent debates on reproductive justice also include the right to bear and raise children and the determination of genetic characteristics of those children.

Complicating this view is the linkage of reproductive rights with social justice developed by organizations advocating for the rights of women of color beginning in the United States during the late 1980s. The concept of reproductive justice arose from recognition of the substantial barriers poor women, racialized women, women with disabilities, and LGBTQ individuals have always encountered in exercising their reproductive rights. This broader conception of reproductive justice, which recognizes that women from marginalized groups face additional obstacles to reproductive self-determination, has since expanded beyond the U.S. context to address obstacles faced by women worldwide.

Reproductive Rights

Reproductive rights have been grounded in the recognition that individuals are entitled to bodily autonomy and the ability to make their own reproductive choices. Autonomy is conventionally defined in terms of individual control over one's body and behavior, analogous to ownership of one's self. This narrow understanding of autonomy and choice obscures the extent to which behaviors and actions are profoundly affected by broader social influences. Relational autonomy offers an alternative understanding of autonomy and selfhood that recognizes that we are both shaped through our relationships with others, while at the same time we are autonomous in not being determined by our relationships (Nedelsky, 2011). Under a relational autonomy framework, reproductive rights cannot be limited to protections for individuals from interference from the state, but must also include necessary supports for bearing and raising children. However, reproductive rights in developed nations do not generally follow a relational autonomy framework.

Conventional debates on reproductive rights have been animated by a number of distinctions that have contributed to informing their scope and content. Central has been the distinction between negative and positive rights and the distinction between procreative and parental rights. More recently, international law sources and norms have also informed the content and scope of reproductive rights.

Traditionally, negative rights are understood as civil and political rights, considered to be guarantees of freedom from state interference. Positive rights are understood in terms of social and economic rights, as affirmative obligations on the state to enable certain rights. In the context of reproductive rights, negative rights would include protections against forced sterilization, for example, while positive rights would require the state to provide access to a minimum standard of sexual and reproductive health care.

It is important to distinguish between procreative and parental rights, since parental rights do not necessarily follow from procreative rights. Definitions and protections for both of these types of rights vary widely in different jurisdictions. For example, procreative rights include whether, how, when, and with whom to procreate. While it is often assumed that parental rights flow automatically from the exercise of procreative rights, in some jurisdictions they do not. This has become especially apparent in the case of determining parental status when assisted reproductive technologies (ARTs) are used and multiple parties are claiming parental status. Biological progenitors and/or surrogates who have an embodied relationship with the resulting child may be denied parental rights in relation to the child with whom they have a procreative relationship. Even in circumstances where ARTs are not used, in some jurisdictions the doctrine of best interests of the child takes precedence over parental rights; for instance, in the case of child abuse, parental substance abuse or incarceration, and in

 http://dx.doi.org/10.1016/B978-0-08-097086-8.86143-7

disputes over child custody in the event of divorce (Meyer et al., 2010; Scott and Emery, 2013). For example, in Canada, the *Divorce Act* mandates that the best interests of the child be the principal consideration in determining child custody arrangements (Branch, 2007). On the other hand, Australia passed the *Family Law Amendment (Shared Parental Responsibility) Act* (2006), which emphasizes parental rights (in the form of shared custody after divorce) above the best interests of the child.

Reproductive rights encompass both procreative and parental rights. Reproductive rights for women include the right to decide whether or not to have children, how many children they will have, and the spacing and timing of pregnancies (Cook et al., 2003). Reproductive rights also include the right to be free of illnesses and other conditions that might interfere with sexual activity and reproduction (Cook et al., 2003). The right to found a family and the right to raise healthy children through providing for their physical, social, emotional, and educational needs are also important reproductive rights (Washenfelder, 2004).

There is increasing awareness within the international human rights community about the need to protect the sexual and reproductive health of women. Women's rights to intimate relations and reproductive choice have been expressly recognized in international human rights law – particularly in the Convention on the Elimination of all Forms of Discrimination against Women (CEDAW) adopted in 1979 by the United Nations General Assembly – in such areas as protections for marital status (CEDAW, Article 16), access to contraception and family planning (CEDAW, Article 12), and pre- and postnatal care (CEDAW, Article 12). Sexual and reproductive rights are protected in various internationally recognized principles of human rights relating to health and self-determination.

Since rights depend on the observance of other rights, this collection of international human rights principles must be interpreted and applied interactively in order to advance women's sexual and reproductive health. Some of the international human rights principles that apply to legal, social, economic, and political rights and which may consequently provide legal grounding for human rights to parenting and reproductive health include: the right to life, liberty, and security of person (Universal Declaration of Human Rights, Article 3); the right to equality and nondiscrimination (Universal Declaration of Human Rights, Article 7); the right to marry and have a family (Universal Declaration of Human Rights, Article 16); the right to the highest standard of attainable health (Universal Declaration of Human Rights, Article 25); the right to reproductive health, understood to include family planning and maternal health services (CEDAW, Article 12); and the right to information and education concerning sexual health, family planning, and reproductive services (CEDAW, Article 12; Article 14b).

Contraception and Abortion

The struggle for reproductive rights in the developed world historically has centered on access to contraception and safe, legal abortions. Contraception in the West has largely been framed as an issue of morality. Support for contraception was equated with support for extramarital sex and from the late 1800s onward, contraception was illegal in Canada and the United States. Contraception was legalized in the United States in 1965, in France in 1967, and in in Canada in 1969. Since then contraception has become increasingly available worldwide (Bullough, 2001).

Contemporary barriers to accessing contraception include cost, requirements for parental consent, differential prescription practices for different groups of women depending on race and socioeconomic status (Borrero et al., 2013), need for prescriptions rather than over-the-counter access, and conscientious objection among prescribers and health care professional service providers (McLeod, 2010). Current controversies in contraception include access to the morning-after pill, safety concerns, and coerced contraception based on race and socioeconomic status as in the case of the Norplant implant controversy. Throughout the 1990s, U.S. legislators attempted to provide financial incentives to welfare recipients who received the Norplant implant. Some judges offered the implants to women as an alternative to jail terms – particularly racialized women and women on welfare. Teenaged girls in predominantly Black schools in the United States were also targeted by campaigns to promote use of the Norplant implant (Roberts, 1997).

Abortion is an enduring source of controversy in the West and its legality varies widely among countries and over time. It has been a rallying point for women's reproductive rights, restricted historically, but with access expanding over time. Despite the trend to liberalized abortion, barriers to access continue to be introduced in many countries, including mandatory waiting periods, biased counseling requirements, and unrestricted conscientious objection among health care providers (Finer and Fine, 2013).

In many European countries, abortion is allowed only during the first trimester; abortions during later stages of pregnancy being allowed only for specific reasons, such as the life or health of the pregnant woman, the occurrence of a sexual offense including rape or incest, or fetal impairment (Boland, 2010). For example, Germany requires a mandatory 3-day waiting period and a counseling session and forbids abortions after the first 12 weeks of pregnancy except in cases of grave threat to the pregnant woman's physical or mental health. Similarly, the Netherlands requires a 5-day waiting period, after which abortion is permitted until fetal viability, legally defined as 24 weeks but usually interpreted as 22 weeks. A notable exception is Northern Ireland, where abortion at any stage of pregnancy remains illegal unless the life of the pregnant woman is at immediate risk or there is a long-term or permanent risk to her physical or mental health (Daniels et al., 2013).

In the United States, abortion law depends on the duration of pregnancy. Abortion is permitted until the point of fetal viability, variously interpreted in different states, with Alabama holding the strictest definition of 19 weeks (Arzuaga and Lee, 2011). Many U.S. states have unsuccessfully attempted to pass laws banning abortion, but have imposed mandatory restrictions such as waiting periods, counseling, and ultrasounds. Canada is unusual in having no criminal laws pertaining to abortion.

Those who oppose abortion generally justify their position through an appeal to the rights of the embryo or fetus.

Supporters of rights to abortion appeal to women's rights to self-determination. Reproductive freedom was foundational to the modern feminist movement of the 1960s and 1970s. Access to contraception and abortion helped to liberate women from unwanted pregnancy. The conventional understanding is that the right to contraception and abortion is fundamentally a negative right based on noninterference in women's reproductive choices by the state. However, this is too narrow a conception of reproductive rights and limits safe access to abortion. As Rodgers and Downie (2006) point out, even in countries where abortion is legal, access can vary widely depending on cost, geographical location, and access to health services.

Fetal Personhood and Maternal Agency

Although laws vary globally, in Australia, the United Kingdom, Canada, and most parts of the United States, legal personhood is only accorded to a child once it exists independently from the mother; the fetus has no legal personhood. However, in many jurisdictions the fetus is granted special legal status as a result of being viewed as a potential person (Harris-Short, 2009). Debates over the status of the fetus occur between those who attribute personhood to the fetus at varying stages of development and those who deny that it has any legal status until it is born, with a range of positions in between.

The debate over fetal protection was active in many countries in the late 1980s and early 1990s and continues today. Women's rights were overwhelmed by the so-called 'protective incarcerations' of pregnant, drug-addicted women, some of whom received nonconsensual medical treatments. Some women whose infants were born testing positive for drugs were prosecuted for harm alleged to have been caused *in utero*. Poor, racialized women have been particularly targeted (Roberts, 1991). Such prosecutions continue in some U.S. states, in addition to repeated unsuccessful attempts to establish legal personhood status for fetuses.

The Supreme Court of Canada has to date refused to assign liability to pregnant women for harms to the fetus before birth. In the case of *Dobson (Litigation Guardian of) v. Dobson* (1999), the court considered whether a fetus born alive and viable could bring a tort action against his biological mother for injuries allegedly caused while *in utero* as a result of her negligent operation of a motor vehicle. Distinguishing between a legal action brought against a pregnant woman by her born alive child and one brought against a third party, Justice Corey wrote that the imposition of liability "may make life for women who are pregnant or who are merely contemplating pregnancy intolerable." The court held that the liberty and equality rights of women would be violated by a finding of liability in these circumstances and that their privacy and autonomy rights would be jeopardized. In *Winnipeg Child and Family Services (Northwest Area) v. D.F.G.* (1997), the Supreme Court of Canada considered whether a pregnant aboriginal woman (Mrs G) addicted to glue sniffing could be involuntarily detained until the birth of her child and forced to undergo treatment for her addiction. A majority of the court held that the fetus has no legal rights until born alive and therefore there was no legal person on whose behalf Mrs G could be detained. Neither the law of tort nor the court's *parens patriae* jurisdiction can be used to detain and treat a pregnant woman for the purpose of preventing harm to an unborn child. Both of these cases reject fetal personhood and reassert women's reproductive autonomy and security of the person.

The concept of fetal viability in law is used to limit reproductive choices for women. Fetal viability refers to a developmental stage in which the fetus can survive outside the womb if it were prematurely delivered. In the groundbreaking U.S. Supreme Court abortion case (*Roe v. Wade*, 1973), the fetus was determined to have limited legal personhood at the point of viability. In *Roe v. Wade* (1973), states could regulate to limit abortions in the third trimester except where they were necessary to save the mother's life. But in the later Supreme Court case (*Casey v. Planned Parenthood*, 1992), the emphasis on the third trimester was changed. Instead, the court ruled that state laws were not to place any undue burden on women seeking abortions up to the point of viability. Viability could arise before the third trimester given advances in technology. As a consequence, fetal viability has been constructed as the moment when a fetus gains personhood status under the law, rather than personhood beginning with birth.

Although fetal personhood and maternal agency are often viewed as competing interests under a traditional liberal conception of subjectivity, a relational understanding of subjectivity allows us to see that the bodily boundaries of fetus and pregnant woman are actually intermingled. Reconceptualizing autonomy through a relational lens allows for the development of laws that recognize a fuller understanding of selfhood as constituted through relationships with other people and social institutions, bodily practices, and beliefs (Downie and Llewellyn, 2011; Nedelsky, 2011). Such a view of the relationship between pregnant woman and fetus is also consistent with postmodern feminist descriptions of the body in which self and other are never fully separated (Haraway, 2013; Shildrick, 1997). However, as Ordolis points out, a relational approach must be reconciled with respect for women's reproductive autonomy. This requires going beyond the inevitably adversarial approach of the courts, recognizing the systemic causes of maternal substance abuse, including discrimination, poverty, and violence, and promoting maternal and fetal health by supporting women's capacity to make healthy choices without eroding their bodily integrity (Ordolis, 2008).

Reproductive Justice

The concept of reproductive justice was developed and principally advocated for by organizations of women of color who were critical of the narrow focus on access to contraception and abortion and called for a broader analysis of the racial, economic, cultural, and structural constraints on women's reproductive choices. These choices for marginalized women have been forcefully curtailed as a result of systematic oppression. According to the reproductive justice movement, the pro-choice paradigm of reproductive rights fails to recognize broader infringements of reproductive rights faced by women of color and aboriginal women, poor women, women with disabilities, and women from other marginalized communities

(Smith, 2005). In this way, the concept of reproductive justice goes beyond choice and promotes women's reproductive self-determination more broadly, recognizing the systematic forms of oppression to which many women are subject.

Women of color, lesbian, bisexual and queer women, poor and disabled women, and women from other marginalized groups have faced obstructions of their reproductive rights, including forced sterilization, restrictions on entering into a legally valid marriage, limitations on access to work to protect reproductive capability, and birth registration rules that impose paternity and fail to recognize maternity (Rodgers, 2007). Sexual sterilization was (and still is) carried out without consent on many groups of women, including women of color and aboriginal women, poor women, women with mental and physical disabilities, and women suspected of being criminally deviant or promiscuous. Historically, eugenics programs attempted to remove unwanted or undesirable characteristics, thought to be hereditary, from society, and operated in a larger context of colonial racism and xenophobia. For example, in Canada, the *Sexual Sterilization Act* in Alberta came into effect in 1928 and was not repealed until 1972 (Grekul et al., 2004). What was widely referred to as the Eugenics Board authorized 4725 sterilizations and carried out 2822 of them (Caulfield and Robertson, 1996). Aboriginal and Métis people were, in particular, targeted by the Eugenics Board.

Women with Disabilities

Women with disabilities are often prevented from participating in sexual, reproductive, and nurturing activities. They often experience double discrimination; regarded by many as asexual and not aspiring to motherhood. Reproductive rights to which women with disabilities face significant barriers include sexual health education, the right to intimate relationships, the right to marry, the right to sexual and reproductive health (including contraception, obstetrical care, and reproductive assistance), and the right to found a family.

Women with disabilities are protected under the United Nations Convention on the Rights of Persons with Disabilities, which guarantees "the same range, quality and standard of free or affordable health care and programmes as provided to other persons, including in the area of sexual and reproductive health and population-based public health programmes" (Article 25a). However, these services are often unavailable (Gibson and Mykitiuk, 2012).

Frequently girls and women with disabilities do not have access to nonjudgmental information and counseling regarding their sexual and reproductive health needs (Quinn et al., 2011). They are often considered not to require comprehensive sexual and reproductive health education because of social prejudice (Esmail et al., 2010). Generic sexual and reproductive health education materials may not provide accurate information about bodily differences in women with disabilities and may not be available in accessible formats. As well, girls and women with intellectual disabilities may not receive adequate information as a result of being infantilized and overprotected (Isler et al., 2009). Health care providers often lack training in sexual health issues relevant to persons with disabilities, medical facilities are often physically inaccessible, and services are often provided in an inaccessible format (Gibson and Mykitiuk, 2012; Gibson and O'Connor, 2010). Additionally, there are obstacles to women with disabilities gaining access to contraceptives and receiving accurate knowledge about their contraceptive options.

Women with disabilities face significant obstacles to social participation, which limit their ability to enter into and enjoy social relationships and express themselves sexually (Lafferty et al., 2012). Women with disabilities who live in institutional settings are often blocked from sexual expression and developing intimate relationships, while those who live independently but require personal assistance may have their privacy negatively impacted. As a result of prevailing social prejudices, most service agencies for people with disabilities have overlooked sexual issues or have deliberately refused to address the sexual needs of people with disabilities (Couldrick et al., 2010).

Similarly, women with disabilities face substantial barriers to parenting. They face difficulty accessing both obstetrical care and ARTs due to discriminatory assumptions about their ability to become parents. Women with disabilities are often viewed as less maternal and unfit to parent, criticized for becoming pregnant, and assumed to be incapable of caring for their children (Silvers, 1998). Mothers with disabilities are often subject to increased surveillance from the child protection system because they are often assumed to be unable to care for their children. Child protection workers may have negative assumptions about women with disabilities due to the prevalence of myths and stereotypes about disability and the child protection system may not be sensitive to the socioeconomic context of some women with disabilities, which may include a lack of disability-related supports and services, under or unemployment, and abuse.

LGBTQ Reproductive Rights

ARTs allow for a broader range of choice in ways of reproducing and in the creation of new family forms. Lesbian, gay, bisexual, and queer individuals often rely on ARTs in order to have genetically related children in the absence of procreative sex. However, they face barriers to accessing ARTs, including prejudice against homosexuality and the high cost of the procedures (Corbett et al., 2013; Greenfeld and Seli, 2013). In addition, laws determining parent/child relationships, where disputes arise in the context of the use of ARTs, often reinscribe a heterosexual nuclear family form and fail to recognize the parental rights of queer family members (Dempsey, 2010).

Lesbians have been able to reproduce, often without medical intervention, through the process of artificial insemination using donor sperm from either anonymous or known donors. Since gay men cannot biologically bear a child, they require the participation of one or sometimes two women in order to produce a child to whom they are genetically related. In some cases, where it is legal, one woman may consent to donor insemination with the sperm of the intended gay father and consent to act as a surrogate mother to enable him to have a child genetically related to him. In other cases, one woman may undergo the medical procedures and risks incurred in *in vitro* fertilization (IVF) in order to produce ova for fertilization,

while a second woman will gestate the embryo(s) and give birth to the baby. In order to have a genetically related child without a female coparent, it is necessary for an intended gay father to procure both an egg donor and surrogate or someone willing to do both often at costs that greatly limit their accessibility (Mitchell and Green, 2007). Adoption may be a less expensive route to gay paternity, but adoption is often more difficult for gay parents, particularly in the case of international adoption (Brodzinsky and Pertman, 2011; Lewin, 2006). The use of known donors (both sperm and ova) and coparenting among lesbian, gay, and bisexual parents of opposite sexes may also be carried out in order to form chosen families, transforming gendered parental roles (Padavic and Butterfield, 2011).

Lesbian and bisexual women in comparison with gay and bisexual men face different obstacles to procreation because acquiring access to donor sperm is frequently easier than accessing donated ova and finding a woman who is willing to gestate. In addition, legal regimes may also construct rules restricting the procreative choices of gay, lesbian, and bisexual parties. For example, in some cases, lesbian women have had their reproductive choices thwarted by demands for legal paternal recognition by sperm donors (Dowd, 2013). Despite the frequent use of assisted reproduction by LGBTQ people, barriers persist, including heteronormative attitudes and discrimination, difficulty accessing genetic material, lack of legal protections for same-sex marriage and parental rights of nonbiological parents, and high costs (Creating Our Families, 2010; Rank, 2010).

Transgender and gender-nonconforming individuals face additional obstacles in exercising reproductive rights. Trans parents challenge conventional gender roles and assumptions, requiring a reconceptualization of pregnancy discrimination law in order to protect the reproductive rights of trans individuals (Karaian, 2013). Since Thomas Beattie entered the public eye as a pregnant trans man in 2008, trans parents have become more visible, but continue to face substantial challenges in exercising reproductive rights due to discrimination and ignorance (Ryan, 2009). They face significant barriers in accessing health care (Bauer et al., 2009), and although trans parenting is underresearched, preliminary studies indicate that ART service providers are unprepared to meet the needs of trans persons (James-Abra, 2012).

Transgender people are also subject to legally prescribed, state-enforced sterilization (Castagnoli, 2010). Sixteen European countries currently do not permit trans persons to legally change their sex without undergoing sterilization; Sweden has recently repealed this requirement (European Union Agency for Fundamental Rights, 2010). Thus, reproductive rights are deeply gendered across a multiplicity of gender identities.

Assisted Human Reproduction

Assisted reproduction allows for the deliberate manipulation of the materials and processes of reproduction in the absence of sexual intercourse. Examples of ARTs include IVF, intracytoplasmic sperm injection (ICSI), insemination with donor sperm, and reliance on third-party reproductive materials and capacities, including sperm and egg provision and gestation. The use of ARTs allows infertile individuals and couples, single women, and people who are lesbian, gay, or transsexual the opportunity to have children to whom they are genetically related. ARTs may also be used, often in combination with preimplantation genetic diagnosis (PGD), by individuals or couples who carry genetic conditions and seek to avoid passing those conditions to their children, or who desire to pass on specific genetic conditions or characteristics to their children.

The use of ARTs expands the realm of reproductive choices and options for some individuals and couples, providing increased opportunities to have a child to whom one is genetically related or with particular genetic characteristics. However, the social, legal, and economic context in which decisions about the use of ARTs are determined, who gets access to them and under what circumstances, raises questions about the nature and scope of reproductive rights. Central to this is an examination of the right to reproduce as a positive right, and what this means not only when the state is called upon to facilitate access to ARTs, but also when exercising one's right to reproduce may involve the participation of another human being. The practice of using ARTs also invites discussion of the reproductive health needs and choices of women who donate ova or gestational services and the concomitant issue of payment for reproductive labor and tissues.

The most well-known reproductive technology is IVF in which a woman's ovaries are stimulated with menotropins to produce multiple oocytes which are removed through transvaginal ultrasonographic-guided needles. Oocytes are then fertilized in petri dishes and one or two transferred to the woman's uterus. Any remaining embryos are cryopreserved for future use, or donated to research, donated for implantation, or discarded once it has been determined that remaining embryos will no longer be needed for an individual's or couple's own reproductive purposes.

Use of embryos in research requires safeguards in order to protect women, who are most directly affected by ARTs. Given the risks of egg retrieval, additional embryos created through IVF should be frozen (cryopreservation) for possible use in future IVF cycles (Nelson et al., 2008). The decisions to end cryopreservation and to donate or discard the embryos should be made separately. Informed consent must be obtained from both the gamete and embryo providers before using embryos for research purposes. Potential donors should be provided with complete information about the research project for which their donated embryos will be used and all details about what will be done with the donated embryos. Potential donors should also be informed about the potential risks and benefits of participating in the research project, including reduction of the embryos available to them for reproductive purposes, the need to potentially undergo another egg donation retrieval cycle, and possible psychological implications of donating embryos. Finally, donors should also be informed that they may withdraw their consent at any time before the embryos are thawed for use in research, and that their medical care will not be affected by their decision about donating embryos for use in research.

Legal definitions of embryos as entities distinct from the bodies of women who may gestate them also raise issues for women's reproductive decision-making abilities. There are limits on how long embryos can remain in storage in the

United Kingdom and Australia; consequently, women have been forced to make disposition decisions about their embryos before they were ready to (Millbank et al., 2012). Options for disposition include destruction, donation for others' reproductive use, and donation for research purposes. Decisions regarding disposition is a significant and frequently unresolved issue for couples with cyropreserved embryos, and very personal conceptualizations of embryos contribute to ambivalence, uncertainty, and difficulty in reaching a decision (Nachtigall et al., 2005).

In circumstances where a woman's eggs are not viable or where she does not have any, donor eggs are required for pregnancy. Countries in the West have divergent regulation on this issue. In Austria, Italy, and Germany egg donation is illegal, while in Canada and France the altruistic donation of eggs is legal. In the United States and in the United Kingdom egg donors may be compensated. However, in the United Kingdom the rate of compensation is fixed and regulated by the Human Fertilization and Embryo Authority, which regulates widely in the realm of assisted reproduction, while in the United States free market principles determine the rate of compensation for egg donation and the practice is widely unregulated. The intimate, time-consuming, and medically risky nature of egg donation has long made egg donors hard to come by. There is, however, an emerging market in human eggs in which women are paid – legally in some jurisdictions, illegally in others – to provide their eggs to intended parents. In order to avoid legal restrictions, women may be paid in one country and undergo egg retrieval in another or, alternatively, intended parents may travel long distances. The market in reproductive tissue raises ethical concerns about the potential exploitation of women who put their health at risk by donating eggs.

Surrogacy is a long-standing ART. Traditional surrogacy (in which the surrogate mother is genetically related to the baby she is carrying) is still sometimes practiced, but in combination with IVF, the use of gestational surrogates is becoming increasingly popular. Gestational surrogacy involves a surrogate mother carrying an embryo produced from the genetic material of the intended mother and father. Surrogacy may be used in cases where an intended mother has uterine difficulties (or no uterus) that prevent her from carrying a child to term, or in the case of gay couples relying on a combination of both an egg donor and a gestational surrogate (or simply a traditional surrogate).

Like egg donation, surrogacy is a controversial practice. It is illegal in many European countries including Germany, France, Spain, and Italy, while commercial surrogacy is illegal in the United Kingdom and Canada. Commercial surrogacy is, however, legal in the United States (Norton et al., 2013). In many of these jurisdictions, there is an unregulated, underground market in surrogacy, and violations of the law are rarely enforced. People seeking surrogates in the West in jurisdictions, where surrogacy is illegal or strictly regulated (or where it is very expensive), may travel to countries including India or Thailand to find commercial surrogates (Hudson et al., 2011).

The use of ARTs by couples and individuals seeking to have children has been increasing since the 1980s. However, barriers to equitable access exist in some jurisdictions due to the high cost of the procedures, formal and informal eligibility criteria, and discriminatory clinic screening practices (Gurmankin et al., 2005; Luce, 2010; Peterson, 2005). In the absence of public funding for ARTs, access is generally restricted to women and couples who have the economic means to pay for the procedures and the associated drug regimen. A number of countries, including Australia, Israel, the United Kingdom, and the province of Quebec in Canada, do publicly fund IVF and ICSI, for example, but there may be restrictions placed on the number of cycles, the age of the woman, or the number of children for which public funding is available.

Ability to pay is not the only impediment to accessing ARTs. Clinics and physicians use a number of criteria to determine eligibility that focus on the potential benefits and risks to the health and safety of the participants based on medical factors, including the participants age and cause of infertility. However, nonmedical criteria have also been used to restrict access to ARTs for persons from a number of marginalized groups, based on disability, race and ethnicity, marital status, and sexual orientation (Kissil and Davey, 2012).

Fertility Preservation

Increased use of ARTs is in many cases a response to infertility. Healthy pregnancies and reproductive lives are part of the larger picture of reproductive freedom, alongside access to abortion care and contraception. Women's fertility may be curtailed by various factors including sexually transmitted infections, age, toxic exposures, smoking, and others. Growing awareness of the impact of chemical exposures on pregnancy is leading to calls for chemical policy reform that protects women's reproductive health and fertility from toxic chemicals (ACOG, 2013; RCOG, 2013). Women from marginalized groups are likely to be substantially more affected by exposures to toxic chemicals (Sze, 2007). Environmental health concerns are an integral and sustainable part of reproductive rights. Stronger regulation of toxic chemicals is required in order to improve reproductive health outcomes.

Reproductive Choice and Prenatal Genetic Testing

Reproductive rights in the developed world have largely been grounded in the recognition that individuals are entitled to bodily autonomy and the ability to make their own reproductive choices. While earlier accounts of reproductive rights were primarily concerned with women's abilities to make safe, legal choices to avoid unwanted procreation, reproductive justice in the contemporary context has been argued to comprise a spectrum of rights that include not only the right to bear and raise children, but also the right to determine the genetic characteristics of those children.

Over the last 20 years there has been a proliferation of diagnostic technologies aimed at identifying and eliminating potential 'abnormalities' in future children (Karpin and Savell, 2012). Such technologies, and their attendant practices, raise questions about the ways in which individuals define and understand concepts of disability and normalcy. In Western culture, a medical model of disability has long dominated mainstream thinking, characterizing disability as not only objectively ascertainable, but also inherently undesirable (Karpin and Savell, 2012). Negative assumptions about

disability have particular relevance to our understanding of the social context in which reproductive choices about the use of prenatal screening and testing technologies are made. In a society where health is highly valued, the conflation of disability with ill health has increased the responsibility of women, and to a lesser extent men, to become informed about the available screening and testing and to evaluate their own, as well as their future progeny's, projected health status (Mykitiuk, 2002).

In order to determine whether a fetus is at risk for diseases involving chromosomal abnormalities, postconception screening tests (usually maternal blood tests or ultrasounds, including nuchal translucency scans) may be used. Conditions frequently tested for include aneuploidy, such as Down's Syndrome, Edwards Syndrome, and Patau Syndrome, as well as spina bifida (Karpin and Savell, 2012). However, the false positive rates of the current screening methods are approximately 5%; thus, in order to obtain a more definitive diagnosis, fetal cells must be acquired through amniocentesis or chorionic villus sampling and then analyzed (Barber, 2013). Each of these methods of prenatal diagnosis (PND) is invasive and carries the risk of miscarriage (Barber, 2013).

PGD provides an alternative to current postconception diagnostic procedures. The technique involves taking a biopsy sample (removing one or two cells) from an embryo that has developed to a minimum of four cells and conducting a genetic analysis thereafter. To date, over 350 chromosomal and genetic abnormalities can be tested for using PGD, including cystic fibrosis, hemophilia, some hereditary cancers, diabetes, and deafness (Karpin and Savell, 2012). Sex and some physical characteristics can also be selected for using PGD, raising concerns that clinicians and patients might try to use the technology to create the so-called 'designer babies.' Nevertheless, the decision to use PGD is usually prompted by a patient query regarding concern over the presence of a hereditary genetic condition in his or her family (Karpin and Savell, 2012). Because PGD is both expensive and invasive, the technology is currently only used by a small number of people worldwide and is often subject to restrictive regulatory regimes that further limit its access.

The legality of PGD testing varies in different countries. Many countries and regions including the United Kingdom, South Australia, New Zealand, and eight European countries (Greece, Spain, France, Denmark, Sweden, Norway, Germany, and the Czech Republic) stipulate that PGD may only be used in the case of 'serious' disease or disability. However, what constitutes a 'serious' disease or disability is often ambiguous in legislation and is typically left up to the determination of clinicians (Karpin and Savell, 2012). Western Australia only permits the use of PGD when it is therapeutic for a particular egg or embryo, while the Victoria region of Australia allows clinicians to determine its use on a case-by-case basis. In the United States no uniform laws exist regulating PGD testing, although health professional organizations have developed best practice guidelines regarding its use. Finally, in the United Kingdom sex selection through PGD for social or cultural reasons is prohibited, but is allowed in order to avoid sex-linked disorders.

Despite regulatory barriers to access, the number of individuals who use PND and PGD is growing. Unlike earlier eugenic practices that were coercive and operated at the level of populations, genetic testing operates at the level of individual pregnancies and is voluntary. Prenatal tests are often promoted as conveying neutral information to prospective parents to facilitate 'informed choices' about their pregnancies. These choices include deciding whether to terminate a pregnancy if testing indicates a risk for a genetic disease, taking measures (where available) during pregnancy to reduce the effects of a genetic disease, and preparing for the birth of child with a genetic disease or disability. Far from neutral, though, a woman's 'choice' cannot be severed from the discourses of risk that surround pregnancy and motherhood (Weir, 2006). Routine screening and testing create an environment in which women are pressured not only to become 'responsible' reproducers, but also to manage their pregnancies to ensure the 'best' possible opportunity for a 'healthy,' 'normal' outcome (Karpin and Savell, 2012). Consequently, there is a danger that those who challenge dominant attitudes about risk and disability may be viewed as reckless if they choose to bring a disabled child to term – complicating the idea that testing is freely chosen (Botkin, 2002; Hensel, 2005).

In this way, the growth of genetic testing increasingly makes pregnant women and their health care providers responsible for deciding whether lives are worth living. It is therefore necessary to recognize how genetic testing, as it is presently practiced, reinforces problematic views of disability as abnormal, undesirable, and as an individual medical problem. Decisions about genetic testing must involve genuine choices by prospective parents that are neither constrained by health care funding nor oversimplified understandings of particular genetic conditions. Otherwise, diagnostic technologies have the potential to hinder, rather than promote, reproductive justice.

Conclusion

Reproductive rights remain contested in developed countries. Technological advancements produce new challenges to reproductive rights. Access to contraception and abortion remain important issues in reproductive rights, along with new issues such as genetic testing and ARTs. It is increasingly recognized that reproductive rights must be understood in the context of broader social justice issues. Consequently, the organization Asian Communities for Reproductive Justice (recently renamed Forward Together), one of the original groups promoting reproductive justice, argues that three frameworks are necessary to address reproductive oppression: reproductive health, dealing with service delivery; reproductive rights, addressing legal issues; and reproductive justice, focusing on movement building (www.forwardtogether.org). Although these frameworks are distinct in their approaches, all three are necessary to uphold the reproductive self-determination of all individuals and to ensure the protection of meaningful reproductive choice for all.

Republicanism: Philosophical Aspects

Abstract

Republicanism is the doctrine that public power should always serve the common good of all those subject to its rule. This raises the question how to do so most effectively, either through particular policies or through constitutional structure ('the republican form of government'). The republican philosophical tradition began with Plato and Aristotle, flowered in the writings of Marcus Tullius Cicero, and reappeared with the revival of learning in such authors as Niccolò Machiavelli, James Harrington, John Adams, and Immanuel Kant. More recently Philip Pettit, Jürgen Habermas, and others have returned to the republican conception of liberty as nondomination, and how to secure this through the rule of law, popular sovereignty, and the checks and balances of well-designed deliberative politics. Republicanism seeks freedom and justice through law and government in pursuit of the common good.

'Republicanism' as a philosophical doctrine begins with the axiom that law and government should always serve the '*res publica*' or common good of the people. 'People' in this context signifies all citizens or (more recently) all participants in the relevant community. The *locus classicus* and most famous manifesto of republican thought is in the philosophical writings of Marcus Tullius Cicero (106–43 BC), above all *de officiis*, *de legibus*, and *de re publica*, in which he defined a republic as the property and project of the '*populus*', when the people come together in pursuit of justice and the common good (*de re publica*, xxxv.39). This standard definition of a republican, repeated by St. Augustine (354–430) (*de civitate Dei* XIX.xxi), John Adams (1735–1826) (1787: p. I.xviii), and many others should be given in full and in Latin, because it remains the foundation and persistent common thread in all republic thought: "*res publica res [est] populi, populus autem non omnis hominum coetus quoquo modo congregatus, sed coetus multitudinis juris consensu et utilitatis communione sociatus*". Which is to say: "a republic is the property of the people – not just of any group of persons jumbled together – but of a *people*, properly speaking united in pursuit of justice and the common good of society as a whole.

While Cicero and the Latin language inaugurated the philosophical discourse of republicanism, Cicero himself (*de officiis*, I.xxv.85) attributed the insight to Plato (423–347 BC), who had argued in his *Politeia* that rulers exist to serve the welfare of all citizens alike (*Politeia*, I.xv. 342 E). Aristotle (384–322 BC) made the same point when he equated justice with the common good (*Politica*, III.iv.7; VII.ii.10), and this became the dominant conception of government, law, and justice through most of European history (Sellers, 1998). Cicero wrote his dialogues *de re publica* and *de legibus* to celebrate and modernize Plato's work on the state and the laws (*de legibus*, II.v.14), and the practical aspects of republican philosophy have remained dominant ever since. It is not enough simply to declare the abstract purpose of serving the common good; one must also propose practical institutions to realize the common good in fact. This 'republican form of government' became the primary object of subsequent republican discourse (Adams, 1776).

Discussion of republican principles and the republican form of government has had a revolutionary impact wherever it has taken hold. By asking 'the great question', "what form of government will compel the formation of good and equal laws, an impartial execution, and faithful interpretation of them, so that citizens may constantly enjoy the benefit of them, and be sure of their continuance" (Adams, 1788), philosophers, lawyers, and statesmen have shaken the governments of Italy, the Netherlands, England, North America, France, and many other nations with demands for 'liberty', 'the rule of law', 'popular sovereignty', 'checks and balances', and other basic requirements of republican government, as established already by Cicero in Rome (Sellers, 1998). Subsequent republicans would add representation, the separation of powers, and other new structural devices to protect public liberty ('*libertas*') and avoid Rome's eventual descent into popular tyranny and military despotism (Hamilton et al., 1787). Contemporary philosophers such as Philip Pettit (1945–) (Pettit, 1997) and Jürgen Habermas (1929–) (Habermas, 1992) have renewed this tradition, with further proposals directed at protecting people everywhere against arbitrary power.

The Republican Tradition

'*Res publica*' was the Romans' term for their state, its public business, all public property, and the purposes these served. The word notoriously evades translation, most often appearing in English as 'commonwealth', or simply (more recently) 'republic', the use preferred here. Cicero and Titus Livius (Livy) (59 BC–AD 17) constructed the first and most influential comprehensively republican ideology, to try to explain how and why the Roman republic had failed to serve the public good. Both agreed that republican institutions collapsed when military expansion and party conflict upset traditional checks and balances between the senate, the magistrates, and the people of Rome.

Cicero and Livy inaugurated a republican tradition of 'liberty' that fortified principled resistance to demagogues, emperors, and kings for the next 2000 years. Niccolò Machiavelli (1469–1527) did the most to revive this republican tradition in Italy, in his *Discorsi sopra la prima deca di Tito Livio* (1517).

The resistance of the Swiss, various Italian cantons, and the United Provinces of the Netherlands to imperial control added practical models for republican liberty, as did the constitutional and theoretical writings of various English authors, in their efforts to restrain or remove their kings during the Civil War and Commonwealth (1642–60), the Glorious Revolution (1688), and the extended British controversies over American Independence (1763–83).

The Republican Revival

Republican political and legal philosophy provides an enduring model for philosophers and lawyers who oppose the domination of arbitrary power. The constitutional controversies of the French and American revolutions left institutional relics, which established republican ideals in the structures of Western politics, with a pervasive commitment to 'liberty' and even (in the United States), a federal 'guarantee' that every state in the Union must enjoy 'a republican form of government' (*United States Constitution*, 1787: Article IV, Section 4). Similar provisions requiring senates and independent judges give republican theorists a practical foundation in the constitutions of most Western democracies. Lawyers such as Frank Michelman (1936–) and Cass Sunstein (1954–) revived republican doctrine in law schools, to justify judicial intervention for the common good, against partisan legislation and political corruption (*Symposium*, 1988).

Philip Pettit inaugurated a similar revival among philosophers, embracing three central claims of the republican tradition: that government must serve the common good; that certain institutional arrangements will do so; and that liberty will be the result (Pettit, 1997). Republicanism, since Cicero has offered a political epistemology for finding the common good, or approximating it as closely as possible. The republican question has not been (in the first instance): 'What is the common good?'; but rather: "Which political procedures will best find and protect the common good, given the possibilities and limitations of history and human nature?" (Sellers, 1991).

Liberty as Nondomination

Republican liberty consists in not being interfered with by other persons or the state, except as regulated by the common good of the people, established by republican politics (Harrington, 1656). This conception of liberty as 'nondomination' contradicts a widely held (but more recent) understanding of liberty as not being interfered with at all. Public and private actions that constrain or influence a person's activities do not restrict republican liberty unless they violate the law or republican principles established to serve the common good of the people as a whole. Republican liberty cannot exist without a republican state because nonrepublics will always dominate their subjects, as masters dominate their slaves.

Domination marks the end of liberty, in republican theory, because domination subjects one person to the arbitrary will of another, without regard for the common good. The unchecked power of the *dominus* (or master) makes his subordinates slaves, whether the master chooses to exercise power or not. Slaves to good masters remain slaves, and dominated, because they have no security against their master's will. States dominate citizens when constitutions give legislatures or public officials the arbitrary power to act without regard for the public welfare. Private individuals dominate others when laws and public officials do not protect citizens against private oppression.

The common good is the measure of domination, and therefore of liberty, in republican political vocabulary, because only the common good distinguishes 'arbitrary' interference from justified state action. *Libertas* (liberty) in Rome signified the status of a free citizen in a republican state. The *res publica* (republic) represented every citizen's common interest in the public good. Restraining citizens equally with just laws in pursuit of the common good enhances their liberty by restraining arbitrary power. Neorepublican doctrine revives liberty as a worthy object of public policy by rescuing the sense in which the word first developed as a political ideal. Liberty is not, as Thomas Hobbes (1588–1679) tendentiously redefined it, the unfettered license to do what one wants, but rather a public shield against uncontrolled license in others. Republican liberty consists in equal subjection to the rule of laws, made for the common good, through the carefully balanced mechanism of a republican form of government. For further references *see* Freedom: Political.

The Common Good

The first difficulty republicans face in finding the common good lies in defining the relevant community. Ancient republics closely restricted their citizenship, excluding women, immigrants, and slaves. Most republicans would now extend citizenship and membership in the *populus* or people to all inhabitants of a given territory. This leaves open the question of boundaries. Cicero endorsed a universal republic or society of all humanity, but also recognized the value of local politics. Cultures and human relationships develop and solidify locally. Therefore, the republican interest in harmony and community implies small homogenous republics, where people will have more in common (Montesquieu, 1748). But the natural diversity of human talents and interests guarantees that small communities will find their own internal minorities to dominate and oppress. Larger republics with greater diversity better protect minorities, by making dominant factions harder to assemble (Hamilton et al., 1787: p. x).

The republican solution to the problem of republican boundaries has been to encourage different levels of nested republics, for different purposes, with different capacities. Immanuel Kant (1724–1804) advocated a federation of national republics, assembled in perpetual peace (Kant, 1795). The formula suggested by the United States and modern European Union has been to entrust the protection of individual human rights and commerce, which local majorities might threaten, to federal suprarepublican authorities, while delegating social and cultural concerns to smaller, more homogenous republics. When regional authorities consistently abuse their powers to oppress local minorities, their oppression implicitly recognizes such minorities as separate people, entitled to separate republican homelands, within the republican federation (Sellers, 2006). For further references *see* Public Interest.

Popular Sovereignty

Republicans realized very early in Rome, and have maintained the principle ever since, that the common good will never be found or maintained without the *imperium populi* or popular sovereignty to support it (Tullius Cicero *Cat*. IV.14; *Phil*. IV.iv.8). Machiavelli credited Cicero with the insight that although the people may be ignorant, they are capable of grasping truth, when good men place the truth before them (Machiavelli, 1517: I.iv.10). The purpose of republican popular sovereignty is not that the people should govern everyday, but rather, as Benjamin Rush (1745–1813) suggested in advocating an American 'republic', that the people should select their rulers themselves. The people exercise their power on election days, then defer to magistrates that they themselves have selected (Rush, 1777).

This republican reliance on popular sovereignty distinguishes republican government from liberalism, which diverged from the republican tradition at the beginning of the nineteenth century (Sellers, 1998). Early liberals rejected popular sovereignty in the wake of the French revolution, while retaining republican commitments to liberty, the rule of law, and certain specific rights against the government (Constant, 1819). Liberals divorced liberty from its basis in public deliberation by distinguishing 'political liberty' from personal independence. This left liberals dependent on judges and magistrates to verify their assertions of rights, and protect individual liberty against the state. Liberalism started as a flight from politics, but found that this implied a new definition of liberty as the ability to do what one wants, without state regulation (Pettit, 1997).

Contemporary liberalism has largely abandoned the fear of democracy that separated liberalism from republicanism in the first place, and most liberals now endorse the widespread political participation of citizens in elections (Rawls, 1993). Republican popular sovereignty never signified democracy in any case, but rather a carefully balanced and controlled mechanism for gathering the insights of all members of society, through a process of public deliberation, in pursuit of the common good. As modern liberals have sought a method of democratic deliberation to legitimate their sense of community, and regulate conflicting private interests, they have increasingly returned to the republican principles and institutions already embedded in Western constitutional democracy.

Checks and Balances

The primary, process-centered challenge for republicans has been to identify those institutions that find and secure the common good best. Popular sovereignty provides access to every citizen's interests and insights, but democracy would become an elective despotism, without checks and balances to restrain it (Pettit, 1999). Cicero blamed the Greeks' misfortunes on the turbulence of their popular assemblies, lacking internal balance or a senate to control them (Tullius Cicero *Flacc*.). Republics since Rome have maintained bicameral legislatures to prevent self-seeking in either assembly (Harrington, 1656: p. 22). Democracy is one of several foundation stones of liberty, not an end in itself.

The necessary checks and balances of republican government prevent public officials from making themselves and not the *res publica* the object the state (Paine, 1792: p. 168). The dispersion of power through bicameralism, federalism, and the separation of powers makes it harder for any one person or faction, including the majority, to wield arbitrary power over others (Pettit, 1997: p. 177). American republicans such as John Adams (1787–8: p. I.ii–iii) and Alexander Hamilton et al. (1787: IX) added representation and the life tenure of judges to bicameralism and checks on governmental powers as basic desiderata of balanced republican institutions. If the people and judges are outside government, they can better control their government's mistakes (Hamilton et al., 1787: p. LXIII).

Modern republicans such as Philip Pettit differ from democrats in viewing democracy as a derivative value, in service to the broader ideal of balanced or 'contested' government (Pettit, 1997: p. 187). All government decisions should be subject to challenge by institutions that prevent private inclinations from ruling public interests and ideas. Republicans have proposed bills of rights, public hearings, and many other devices designed to constrain and channel public decision making, so that ordinary citizens may influence their government's decisions, without diverting the public purposes of the state. For further references *see* Constitutionalism.

The Rule of Law

The '*imperia legum*' or 'rule of laws and not of men' protects republican liberty by forestalling arbitrary power. Republican authors from Livy to Pettit have protected the moral element in the republican concept of 'law' against the simplifications of legal positivists, beginning with Thomas Hobbes. Laws secure liberty against domination by delimiting and protecting the line across which private or state behavior violates individual autonomy against the common good. Cicero insisted that such laws must serve the public welfare (*populi utilitas*) not the public will (*populi voluntas*) (Tullius Cicero *Sulla* 25) because votes cannot alter the natural laws of justice (Tullius Cicero *Leg*. I.xvi. 44). Republics require institutions that will find justice by securing the common good.

The empire-of-law condition of republican government entails that laws should be publicly promulgated, intelligible, consistent, stable, general, and apply to everyone, including the legislators themselves. This prevents arbitrary decisions by public officials, by subjecting their will to known constraints and purposes. Republics maintain a general presumption that government action, when needed, will operate by law, not by ad hoc or *ex post* decisions. All agencies of government must act through principled, regulated structures, maintaining the 'due process' of laws to prevent the abuse of governmental power (Pettit, 1997: pp. 174–175).

Codifying the law in every detail will not be possible or desirable. Some discretion must remain, but subject to the dispersion-of-power and popular sovereignty procedures that generate republican laws in the first place. Discretion subject to constraints against arbitrariness may sometimes secure the common good, but unlimited discretion produces mistakes about justice, through the natural partiality and limited viewpoint of any individual decision maker. The republican rule of law protects liberty by respecting the welfare of every member of society, pooling their insights to secure the common good of

the people. Legislation is the public reason of the republic, protecting citizens' liberty against private power (Harrington, 1656: pp. 19–20).

Neorepublican Ideals

Contemporary philosophical republicanism reasserts the republican conception of liberty, proposing new republican institutions to support republican liberty in the modern multicultural state. Philip Pettit has given the most detailed proposal for neorepublican politics, supplanting the Benthamite liberal opposition of 'negative' and 'positive' liberty with older republican conceptions of liberty as nondomination, and protection against arbitrary power (Pettit, 1997). Pettit understands arbitrary power ('*arbitrium*') to include any action against the 'interests and ideas' of those who suffer interference. This surpasses the old republican standard, which measured arbitrary power by its violation of an objective public, common, or collective good.

Neorepublican deference to private interests and ideas reflects the residual liberal commitment to moral pluralism and cultural diversity. This enduring hesitation to overrule anyone's personal ideas makes the revised standard of nondomination very strong. Interference or influence over others' choices becomes domination unless it tracks their private values. This introduces a subjective element into republican doctrine. Older republican ideals tolerated hierarchy and private influences when toleration served the common good of all citizens.

Neorepublican rhetoric describes the state as seeking to *promote* freedom as nondomination, where older republicans would have understood republican pursuit of the common good simply to *be* freedom as nondomination. The difference lies in the pluralistic language of the newer theories. Some suggest that immigrant groups and minority cultures will maintain their separate identities in republics, because republics help to preserve hereditary differences within the larger culture (Pettit, 1997: p. 144). This represents a significant departure from traditional doctrine. Republics exist precisely to create and maintain an overarching culture that embraces all citizens. This necessarily influences and discourages dissenting subcultures by promoting an image of national unity, which will tend to assimilate minority perspectives.

Neorepublican Institutions

The neorepublican commitment to pluralism encourages a greater emphasis on counter-majoritarian aspects of republican popular sovereignty (Pettit, 1997; *Symposium*, 1988). Neorepublicans embrace the empire-of-law condition of republican government and the dispersion-of-power constraint, but they often seek to displace public decision making onto independent panels of social scientists or courts (Pettit, 1997; Sunstein, 1993; *Symposium*, 1988). This favors 'contestability' over consensus to limit the weight of unified public opinion.

Neorepublicans do not endorse interest-group pluralism in the classical amoral sense of liberal democracy, but their concept of representation favors cultural minorities. Some believe that public policy should be able to be justified according to the lights of every member of society (Pettit, 1997: p. 169). This overstates the value of mistaken perceptions of the good. Republican government differs from liberal democracy precisely in that it offers a deliberative technique for overruling mistaken views, while allowing constructive dissent by those who oppose the consensus.

Traditional republics maintained geographical representation to encourage the development of local communities. Most recent proposals prefer religious, cultural, or sexual diversity. Popular elections now seem too crude to identify administrative competence, or to guarantee minimum statistical representation for every stakeholder grouping (Pettit, 1997: p. 192). Neorepublicans often propose deliberation among statistically selected 'representative' officials, in place of elected representatives or public assemblies. This leads to difficulties in identifying which subcultures or stakeholder 'groups' to represent. Most people have many such partial or self-defined sources of identity.

The People

The fundamental republican conception of the common good encourages social solidarity by seeking a community of interest among the *populus* or people of any given republic. Cicero described republics as the property of a people (*res populi*), in the most influential and frequently repeated passage in the republican canon. A *populus* is not just any collection of humans, but a partnership about justice, in pursuit of the common good (Tullius Cicero *Rep*. I.xxv.39). There will be no republic without people and no people (in the fullest sense) without republic, which is to say the mutual recognition of common citizenship (fraternity) and the equal importance (equality) of all citizens in the eyes of the state.

The concept of peoples represents the most contested element in contemporary republican doctrine, and the most likely source of disagreement between neorepublican philosophers. The United Nations Charter recognized the republican principle of self-determination of peoples (Article I (2)), implying a people's right 'freely (to) determine their political status' (International Covenant on Civil and Political Rights 1966, Article 1). This gives the republican identity a practical importance in international politics, implying that recognized status as 'people' entail some degree of political separation. The salient examples of liberated 'peoples' have been the inhabitants of colonial territories, who constitute peoples in international law for the purpose of pursuing their independence from imperial domination.

Some neorepublicans would separate the national and territorial principles to create politically separate republican peoples on the basis of ethnic, religious, or linguistic affinities within larger multinational empires. Different laws would apply to different subjects of the overarching state, according to their different internal 'citizenship' or status. This violates the republican principle of equal citizenship to achieve the republican ambition of social solidarity among state-maintained subgroups of the population. Traditional republican doctrine would insist that all citizens enjoy the same privileges and immunities in their public capacities, while permitting private initiatives to pursue elective affinities. This protects (but may subtly discourage) private diversity, because the people, as public citizens, will be the same under law.

Republican Philosophy

Republican philosophy since Cicero has sought to construct a harmony of interests and common sense of justice among citizens through the 'empire of laws and not of men'. Republican laws draw the line between liberty and license, in pursuit of the common good. Republican theory seeks to find and establish good laws, by discovering the principles and basic structure that serve the *res publica* best. So although republican philosophy begins, as Thomas Paine (1737–1809) put it, by making the '*res publica*, the public affairs, or the public good' the object of all governments, and 'republican government is no other than government established and conducted for the interest of the public' (Paine, 1792: p. 168), the idea of the republic entails a constellation of political structures to secure republican legislation, embedded in 2000 years of republican tradition, derived from Rome.

The republican commitment to political institutions that protect liberty challenges the later 'liberal' flight from politics after the French revolution. Former republicans such as Benjamin Constant (1767–1830) hoped by securing certain rights or liberties to protect their own private liberty against the state. But republican philosophy recognizes the futility of 'rights' without power. Republican doctrine offers a political epistemology to discover and protect public justice and fundamental human rights. Republicans believe that without popular sovereignty, the rule of law, deliberative senators, elected executives, independent judges, a representative popular assembly, and proper checks and balances, the people cannot know or enjoy their rights and duties to each other, or to the state. The basic desiderata of republican government may appear more (or less) important in different contexts, so that even a monarchy could seem nearly 'republican' when limited by two independent branches in the legislature, and subject to the rule of law (Adams, 1787–8: pp. I. xxi–xxii). Contemporary republican philosophers adapt republican principles to new circumstances to protect public liberty against improper domination ('*dominium*') by private interests, or the arbitrary government ('*imperium*') of the state (Pettit, 1997). What makes such theories republican is their fundamental commitment to the common good, and to the political structures that support the *res publica* best. Republican philosophy is a theory of freedom and government, or rather of freedom through government, to secure a shared sense of justice, in pursuit of the common good. Republicans believe that there can be no justice without community, no liberty without the law.

Abstract

A reputation exists in the form of a shared image that develops within networks. It can vary along three dimensions: from high to low, in size, and in longevity. Difference can be estimated either from survey responses or from indicators in documents. Reputations reduce uncertainty about what to expect from those who hold them. It influences both a person's own behavior and one's treatment by others. They follow trajectories of different length, some of which extend beyond a lifetime.

A reputation exists in the form of an image shared within some public. Applied to a person, it identifies "not an intrinsic quality he possesses but rather the opinion other people have of him [or her]" (Bailey, 1971, p. 2). One can also refer to an institution, organization, professional group (or its leadership), and by extension to just about anything rated or ranked like a dining establishment, a vintage year of wine, a neighborhood, or a resort in which to take a vacation along with much else. All these reputations are socially constructed. They may or may not be deserved and are always open to challenge. But, as long as they endure, they are real in their consequences.

Overview

Over 300 years ago, when John Locke referred to the "law of opinion and reputation," he highlighted how much reputations were a part of the small politics of everyday life ([1690] 1894, p. 479). To keep them in good reputation, people do accommodate to the opinions and rules subscribed to by those with whom they converse or otherwise interact. Adam Smith, a century later, argued in a similar vein when he located the love of virtue in the desire for "being what ought to be approved of." The success of persons who possess none of the privileges associated with noble lineage or inherited wealth "almost always depends upon the favor and good opinion of their neighbors and equals. Without a tolerably regular conduct, these can very seldom be obtained" (1804, p. I, 123 f). From a strictly economic perspective, moreover, a reputation constitutes a valuable property. It can grow or diminish but its value is real enough for anyone who feels his or her good name has been unjustly sullied by malicious or slanderous statements can seek redress through the courts even if not always successfully. And tax laws in some countries allow the corporate write-off of expenditures for building and protecting the reputation of their company or its brand name. From a broader social and cultural perspective, a reputation can be conceptualized, as Bourdieu (1992) has, as a form of symbolic capital validated against the perceptions of those in the know. The criteria by which they are judged vary among fields. The main one in economics is reliability or trustworthiness; in politics reputations involve the ability to mobilize support; what counts most in the social–cultural area is the quality of the achievement attributed to the target.

A significant body of research, much of it by economists on the gains an organization reaps from a good reputation and policies to preserve it but also by game theorists in probes of how an opponent's reputation influences an experimental subject's own strategy, has been published in recent years. An alternative approach to the subject is that of Kenneth H. Craik, a social psychologist who, as an outgrowth of the work of his institute on personality assessment, is more focused on how individuals develop reputations and how these evolve. The conceptual model presented in his book (2009), meant as a road map, takes as its point of departure the often ignored fact that people's appraisal of someone's beliefs and abilities, not necessarily of someone they know personally or based on what they actually know, are not just based on their own observations but often even more on what they hear others espouse until accepted as common 'knowledge.'

The Craik model incorporates three components. The first is visibility. One can speak of a reputation only when its carrier has a recognizable identity as a person (and I would add, organization, work of art, or other object) that is shared. This visibility, regardless of how restrictive or widely diffused, remains abstract, without content, and does not amount to a judgment in any sense. Reputational networks, the channels through which information about someone or something circulates, is the second critical component. Usually they extend beyond the circle of mutually known acquaintances to include people whose sole source is what they heard about from others, read about, or followed on television. Each individual participates in a network of his or her own making. The impressions they form, and consequently the reputation based on them, are apt to be greatest among people connected to the same network. This takes us to the third component, the distributive rather the discursive aspect, of the model. The contents that flow through the network end up in personal 'storage bins,' as Craik calls them, from which they can pass on whatever seems relevant to them as well as what others have to offer. After the requisite sifting, collation, and corrections people form the image we commonly designate as reputations. They remain subject to change as new information becomes available.

Reputations vary along three dimensions: Most attention has gone to the position of person or object's position on a hierarchical scale. Those ranking high have gained general respect, enjoy credibility, are free to exercise authority, admired

for their exceptional skill, and so forth. The list is long. Reputations, high or low, are also subject to lateral ranking with placement determined by the range within which a name is both visible and associated with certain qualities or achievements. Some terminological distinctions between these two aspects are called for. To meet this need, Lang and Lang (1990) proposed that reputations within some kind of in-group, such as a circle of personal acquaintances, a local neighborhood, professional peers, or other in-group, be designated 'recognition' and that those and the extent of its circulation throughout society 'renown.' While terms imply positive or favorable rankings, some earn a reputation not for good deeds or desirable traits but for something repellent and therefore to be avoided. To designate these two types on the negative side of the hierarchical scale but otherwise equivalent, we add another pair of terms to the lexicon: 'disrepute' for a bad reputation among peers and 'notoriety' that bad reputation is more widely diffused within a larger population.

The third temporal dimension indexes the duration of a reputation over time. Not only is its content apt to change as new information surfaces but revelations that no one ever expected can cause an idol to fall and enable some despised villains to redeem themselves. Most lifetime renown and notoriety suffer gradual decay because of competition from new entrants into severely limited public space ever more crowded because of the inexorable entry of new generations. As the surviving number of people with personal memories of predecessors passes away, they are bound to lose out to successors that compete for their place. Sooner or later, their reputation comes to depend exclusively on the preservation of the secondary evidence contained in written documents and other material textual residues of the past to become part of an established canon clamoring for recognition from practically everybody. The few that, once they have faded from the collective memory, are later unearthed to recover their former place, are indeed the exceptions.

Reputations, in short, follow different trajectories. At one extreme of the continuum are the 'celebrities' that suddenly burst on the scene apparently from nowhere to enjoy instant fame only to sink back quickly into obscurity, after which they are no longer of interest to anyone except for historians professionally specialized to dig into the past in order to ferret out what has been forgotten. The life span of a celebrity is short. The level of 'eminence' attained by the truly great who proved to be groundbreaking eludes them. The counterparts of both celebrity and eminence, which occupy the positive side of the hierarchical dimension, are 'ignominy,' such as the short-lived outrage triggered by something heinous, denotes a short public reaction. It represents the negative counterpart of celebrity and contrasts with the longer lasting 'infamy' associated with historical memories stigmatized as evil or as undeserved tragedies (cf Fine, 2001). The categories are arrayed in the accompanying diagram (see **Figure 1**).

Ascertaining a Reputation

A theory and a set of categories, if they are orient researchers, must be accompanied by indicators that signal the variable characteristics of the subject to which they apply. For reputations this requirement calls for methods and tools by and to locate or at least estimate positions on the separate scales in terms of who shares the reputation and the qualities they refer to. The two aspects are often fused.

The 'Who?' question demands adequate definition of the social circle within which the reputation is shared. Size does make a difference here. The reputation of the members of a family or a village small enough for every member to know everyone else is based on mutual recognition of what praiseworthy attributes of the object and of its defects draw disdain. The renown or notoriety acquired within a multitude too large and too dispersed for much interaction among those involved develops without, or even in spite of, the personal acquaintance a few among them may have with the object. Because reputations often differ between from social circle to circle, according to the knowledge available to each, a measure not explicit about who shares it – whether it is by people in general or only within a delimited group of insiders, within some self-selected category of connoisseurs, fans, or followers distinguishable only by their unusually high interest in the particular field or object being rated – is of little use.

The 'What?' question refers more to the vertical dimension. The reputation of an object evolves from the circulation of information not about some abstract quality but some particular mode of behavior, skill, deed, or achievement people attribute to it. Where the criterion for what is best, greatest, or most entitled to admiration are left vague, as it has occasionally been, the meaning of the findings can be hard to interpret.

Indicators used for measurement in past studies are essentially of two kinds: those tapping directly into the just mentioned storage bins by surveying the opinions within the relevant social circle and attempts at the quantification of evidence in documents of what these opinions are. To specify the quality on which the objects are ranked or rated as positive or negative is always helpful. The reliability of the findings obtained by either method will be greatest for people coming in some contact with one another. This holds even for reputations not actually earned but based on malicious rumors refuted too late to save an innocent from being pilloried. A method developed by J. L. Moreno, which he named sociometry, relied on peer ratings by members of some group as the best on something or whom they collectively would prefer for

	Lateral (expansion)	**Vertical (status)**	**Temporal (duration in time)**	
High	*Recognition*	*Renown*	*Celebrity*	*Eminence*
Low	*Disrepute*	*Notoriety*	*Ignominy*	*Infamy*

Figure 1 Types by Reputational Dimension

some role. Widely used in the selection of leaders, the method proved its value as a predictor of future performance. The selections by the members of groups more dispersed but frequently trading information, such as the colleagues in some field, also exhibit a fairly high level of convergence, but leave more room for strong disagreement by a few deviants.

The significance of this kind of informal consensus becomes more problematic the farther removed those queried are from the ones on whom they pass judgment, of which the national polls conducted for years asking respondents to name the man and also the woman they most admired, provide an extreme example. Given the freedom of respondents to nominate anyone alive, their choices have always been widely scattered but with the president and the first lady almost always heading the list. Their consistently high ranking, as well as of other highly placed names, has as much to do with the prominent coverage of these two in the news media as with the degree of respect they enjoy in the public sphere or, for that matter, among the political activists who constitute their particular reputational community. It is, however, a measure – although perhaps a somewhat crude one – of where the White House occupants place among a very small number of celebrities, or infamous villains, about whom just about everyone is prepared to express an opinion and, although correlated with measures of presidential approval and performance by this same public, should be mistaken for their equivalent. An open question that leaves respondents free to mention whoever comes to mind is, to say the least, of dubious value as a measure of public reputation.

This caveat does not extend to responses to similar queries addressed to highly qualified experts. Even when the sample of respondents is small and purposively selected, it does represent an effort to replicate what the providers of popular entertainment began to probe decades ago when they first sponsored audience surveys that asked people to state their 'favorites' among the diverse offerings and sources available to them. When seeking a meaningful appraisal of historical figures, there really is no-good alternative to relying specialists. A pioneer of this genre is the study by Arthur M. Schlesinger, a Harvard historian, of American presidents, conducted in the Roosevelt era when he sent a questionnaire to 55 colleagues, all them experts on the presidency, calling on them to place each occupant of the office into one of five categories ranging from 'great' to 'failure.' In the intervening decades, his study has been closely replicated by his historian son (Schlesinger, 1997). Still others contacted larger samples with more detailed questionnaires and more refined measures only to find that the same three – Washington, Lincoln, and Franklin D. Roosevelt – consistently placed at the top, although not always in the same order. Choices of the best and worst presidents have also remained fairly stable with more fluctuation among those ranked in-between, mostly incumbents who neither weathered a serious national crisis nor failed in some obvious way. Most striking among the changes has been the steady rise in reputation of Eisenhower as new information about his presidency has come to light.

More studies have been turning to nominations and/or ratings by respondents with some qualification as insiders to estimate reputations in more restricted realms. They include the rankings of major corporations have earned among business leaders by their exemplary performance, of judiciary figures considered outstanding by their peers, and of the top academic departments as rated by other academics in the same discipline, all of them with better access to facts than the rest of the population. As the practice has spread, the method has been refined. In a recent survey, underwritten by the federally sponsored National Foundation of Science, the open question was replaced by a meticulously designed questionnaire calling on academics in each of several to rank departments in their own discipline. All recipients were urged to respond but given a "don't know" option for any about which they felt insufficiently informed. The resulting rankings correlated with productivity, in terms of research productivity, but also turned up some discrepancies between this one and several other 'objective' indicators of departmental quality (*see* Scientometrics).

Many prefer documentary indicators of current reputation as also the signals of past fame to be found not only in surviving residues from the past, mostly in writing, but also in surviving shrines, statues, sacred objects, and even coins that celebrate a deceased. Insofar writers have been the primary purveyors of fame, how often a member of some group or category of subjects turns up in the literary sources scanned seems acceptable as a measure of the public regard. To be sure, characters not at all honorable or likable, can also arouse interest in their life histories but are less likely to be the subject of full-length biographies than those recognized as heroes and high achievers. There is more information on them and there are more past acquaintances happy to provide personal testimony. Rarely do less than stellar figures offer quite this enticement. Hence, the number of full-length biographies does at best identify only the most famous. Too many of the rest would fall into the 'none' or 'only one category' for this ranking to be of much use. Obviously, no single documentary indicator can possibly fit all. To cast one's net widely is always a good idea.

Documentary indicators discriminate best when limited to a specific field of endeavor or some recognized category of practitioners with some limits set on the time frame. When James R. Beniger (1990), a sociologist, scanned the authoritative encyclopedia of communication with contributions by the established experts in its subfields to estimate greatness from the number of mentions and pages devoted to each, the ranking he came up with turned out to be mildly surprising. A handful from the past, several from long ago, came out ahead of even the most distinguished scholars in this burgeoning field. Randall Collins (1998), another sociologist, in a truly magisterial study, used a similar method, to sort out the philosophers that were the real luminaries with influence on their contemporaries and whose ideas continue to be of great interest from the large number of lesser lights working in roughly the same time period.

For creative artists, an indicator as discriminating, and possibly more than the writings about them, is the fate of their works. Paintings, sculptures as well as prints, and even drawings from the hand of the 'great' masters usually occupy the most prominent places in exhibitions. The museums that own them devote a good part of their conservation budgets to protect and preserve them for posterity. In this they there motivated partly by their rarity and the high interest in them.

Whenever one appears on the art market, curators and wealthy collectors vie for it. They drive up the price to a level out of line with the practical utility of the object or with the labor and value of the materials that went into it. The high price the work commands is determined almost completely by the reputation of its creator. If ever a presumed masterpiece is exposed as a fake, as sometimes happens, or reattributed to one of the master's pupils, its market value plummets. The price premium exacted by the original over the same work, identical with the former in every other respect, disappears. This phenomenon testifies to the validity of reputational rankings of artists derived from the prices they achieve on the art market.

The performing arts allow for no similar distinction between an original premiere and a repeat performance. The longer a play runs or the more often a musical piece is performed the greater the boost to the reputation of its creator. The better indicator here is to be found in the frequency with which a work by a composer finds a place in the repertory of major orchestras or a playwright in the repertories of Broadway, London, and other centrally located theaters. Fashions come and go, and repertories change accordingly. The fairly few works granted canonical status may move down a couple of notches but are unlikely to disappear into the abundant archives of epigonal work, some of which may have had a highly successful premiere prior to receding into oblivion. Repertories often do, however, involve a tacit compromise between the appraisals shared by professionals and demands for work high enough in popular appeal to be a magnet strong enough to draw audiences of a size sufficient to assure the financial survival of the organization on whom they themselves depend. This need has been only somewhat less of a problem in the museum world, where art experts have more control over choices but where it still takes a blockbuster exhibition to bring in the crowds to impress sponsors and attract donors but where high costs, traceable to the scarcity of original masterpieces, are the primary constraint.

Performances, in contrast to the visual arts, do not even have to be 'live.' In fact, sales of recordings, not just of every hit but of the more established composers, playwrights, and performers, not only provide a meaningful measure of their contemporary renown. These data can also lead to potentially interesting findings about the few who survive in the collective memory.

The most 'democratic' of indicators are the frequencies of citation. It is widely used in the knowledge industry, where reference by authors to prior findings relevant to their own work, is an established practice. The utility of this measure for ranking leading scholars in the various academic fields has been pretty much institutionalized. Tenure committees, department heads, and deans in universities refer to it as one among other criteria for deciding who is deserving of a permanent appointment or the best on a short list of highly qualified applicants for an opening. Several indices listing all citations in publications of the professional literature in most disciplines available for half-a-century or more have since gone online for easier access.

Formal honors, such as prizes and election to honorary societies, are less satisfactory indicators of reputations. Some are simply too exclusive to pick more than a small number from an overwhelmingly large pool. Such are the Nobel prizes. Whenever awarded, which they are but once a year, they attract worldwide attention. Since only the still living qualify, the prematurely and unexpectedly deceased loose out, not for lack of the necessary qualifications but on grounds unrelated to the informal honors peers have bestowed on them in the course of an extended career. Selection into the Academy of France, with places for a maximum of 50 members, is similarly restricted to none but the most highly esteemed scientists as they are, in various ways, for many other honors granted only for the highest achievements in the given field within a predefined period. These awards are of no help in discriminating among the runner ups. In addition there is the multitude of potential aspirants whose names never reach the judges who make the final selections, often among nearly equally qualified candidates. Not having a truly objective measuring rod. Immediate unanimity is rare and the final selection often the result of negotiations and compromise.

Nor can their individual judgments be totally free from idiosyncratic preferences – political or personal – of their own, such as may be only tangentially related to what the award is intended to honor. Nor can one even expect these judges to peruse and review personally the qualifications of every prospective candidate. Most pools are simply too large for their limited time and capabilities. To whittle down the numbers to something manageable, most juries rely on preliminary screening by assumedly qualified gatekeepers. This may work for some but for some awards, such as the Oscars annually dispensed by the American movie industry, the process can become hectic. The initial selections are ballot. Some hundreds and more are eligible because of their professional roles in the making of films. Whatever the specific procedures, they leave little room for discussion among screeners to give them opportunity to fill any gaps in their knowledge and correct what misconceptions they may have. When the final jury meets, the best it can do is adjudicate among the remaining candidates. Meanwhile, the recent proliferation of all kinds of awards, many funded by donors eager for publicity, is not very effective as a countertrend. Many of them are so specific and made by so small a constituency that the sheer number amassed by any has lost most of its value as an indicator of the recipient's general standing.

Effects of Reputation

A wide range of empirical work highlights how having a reputation affects that person's own behavior as well as its influence on the behavior of others toward that same person. Fear of doing damage to one's own reputation acts as a deterrent – against selling shoddy goods, harming others while pursuing one's own short-term interest, and all kinds of wrongdoing that most people prefer not to be caught in. Its deterrent influence garners strength when the same two parties engage in repeated dealings over an extended time and, not surprisingly, is generally more effective on people involved in dense social networks or, better yet, among the members of an intimate group, in which they are well-known and with whom they have built warm relationships that they treasure. It certainly is more effective in such a setting than under conditions of partial anonymity. Further and to the extent that a person's reputation has been incorporated into their personal identity, they will be

even more motivated to go out of their way to live up to it by refraining from anything that could raise doubt in the mind of other whether are really the kind of person they want them to think that they are. Nevertheless and contrary to the contention of Adam Smith, which has been seconded by many economists, a reputation is not invariably an incentive for 'good' behavior, not because the process they identified does not work as they see it but rather because of the occasional existence of motives in competition with those posited by them. Thus, for a tyrant or a bully the ability to instill fear can to override concern that this might never strike people as morally upright. Coercive measures that bring desirable results can indeed be more gratifying than blind adhesion to the moral prescriptions most people support as a matter of principle without regard for what the consequences.

Persons greatly concerned about the reputation they project, especially performers and professionals whose fortune depends on their being in the limelight, may be moved to call on spokespersons with special expertise. This same motive could also tempt some to making false claims and to doctor their records which, if their fabrications were ever to come out would bring them infamy instead of approbation for which they are thirsting. Behavior toward adversaries is governed by much the same logic. A state involved in a dispute with another will be disinclined to yield "on a series of issues when matters at stake are not critical... may [make] it difficult to communicate to the other just when a vital issue has been reached" but inclined to act forcefully for no other reason than to retain its "reputation for action" (Schelling, 1966, p. 124). A more recent researcher concluded on the basis of an elaborate statistical analysis of more than 1300 international crises accompanied by threat of force that a state's reputation for honesty or bluffing was an influence on its reputation (Sartori, 2005).

The effect of one's own reputation on the behavior of others has been subject to intensive experimental examination, most often by game theorists guided by formal models of a prisoner's dilemma. Just how well a game repeatedly played in social psychological laboratories played by the same two players approximates the complexities of real life must remain an open question. Whatever the final answer, these experiments at least point in the right direction. By showing how subjects confronted with a deliberately ambiguous situation – due to their uncertainty over whether the other 'prisoner' will confess – this body of research contains ample documentation of the signal importance of a reputation for trustworthiness whether explicitly assigned by the experimenter or one that the subjects themselves inferred from the pattern of behavior they were able to observe on their own. The development of trust, even when there seems no rational basis for it, fosters cooperation.

The above is a guiding principle in a good part of the world of commerce, where people have little or no personal knowledge of the trustworthiness of the many strangers they deal with. All too often reputations, whether by word-of-mouth or formal endorsements, are the main source of the reassurance for people in deciding what to buy, how much to pay for it, safe places to invest, the college likely to offer the best educational experience, and so forth. Mass advertising via the media and, more recently, over the Internet also has an important part in the process even for people not aware of its influence. A good reputation or being associated with a respected band name is as much of an asset for a company as name recognition and an appealing personality are for a political leader. Groups and institutions are under the same duress. Nor are interactions between enemies trading threats instead of goods and votes unconcerned over how they are perceived by the other. In the Cold War period, the two major powers were maneuvering to gain an advantage but anxious to avoid a catastrophic outcome, they gave a lot of weight in planning their every move both to the reputation they had constructed from their opponent's past behavior in similar situations and to how their own moves might affect the image of themselves they had been trying to convey to their opponent. Neither wanted to act out character and risk a wrong response.

On the Internet, where the parties to a transaction are anonymous, an entirely different situation prevails. The participants in Internet auctions are not at all connected so as to be able to circulate the information about sellers needed to develop a good or bad reputation. For buyers on eBay the main source of reassurance is the posted feedback previously left by other customers of the seller and, vice versa, by sellers about buyers. They are, however, a very imperfect proxy for reputations. Their greatest plus is for researchers. They give them access to a database of a sufficient magnitude for statistically reliable findings. Studies, among them a randomized and controlled field experiment of transactions, confirm that sellers with near-perfect feedback ratings generally realize higher prices, especially for more expensive items and where the buyer also incurred some risk. There are other studies that, as far as they go, confirm that negative ratings, while harming a seller in the short run, make little difference over the longer run and that a very positive reputation, which takes longer to build, has more staying power.

An increasing number of smaller but highly competitive businesses – book sellers, hotels, restaurants, etc. have likewise been exploiting the improved versatility of the Internet with invitations for customer feedback that end up on a website, not necessary their own but those of rating agencies. Reputations derived without interaction among customers oare clientele are less reliable than reputation grounded in pooled experience. Participants in eBay, for example, as free to opt out and re-register under a new alias. Nor are yet the means to prevent anyone from mobilizing friends, relatives, or employees to sing their praise on Internet sites like Angies List or Yelp, two agencies whose activities border too closely on advertising in the form of the Good Housekeeping seal of approval during earlier period. A genuine reputation in the commercial realm functions much like an established brand name that allows its owner to extract some price premium over a generic product.

On the other hand, the advantages of a reputation once established tend to be cumulative. This was shown by Robert K. Merton (1967) to hold for a large part of the knowledge industry when he observed that the more distinguished scientists receive a disproportionate amount of the credit for discoveries that result from jointly published research conducted in close collaboration with others. Another researcher found evidence in his study of information exchange among the scientists employed in the same company that, when one of them contacts another to request for information meant to

advance a project of his or her own, the one more renowned stands a better chance to receive a helpful answer than a lesser one (Ensign, 2009). On the institutional level, elite universities are better able to recruit higher a quality faculty, not only because of its high salaries and ample resources but equally because applicants expect more from the presence of especially distinguished colleagues, which in turn acts as a magnet for prospective donors, the best students, thereby adding to its prestige. Nor can we entirely rule out its influence on reviewers of grants. Submissions by scientists to the Australian Research Council received somewhat higher ratings (Jayasinghe et al., 2003, pp. 279–300). In these contexts, the multiple advantages of a reputation are of quite a different kind (for a discussion of academic reputation *see* Scientometrics).

But nowhere are the returns from a good reputation greater than in the arts, where values are somewhat intangible, subject to fashion, highly dependent on critical and public endorsement (Moulin, 1987). When paintings certified by art experts as originals by the seventeenth Dutch master Jan Vermeer were finally exposed as a modern forgery by Han van Meegeren, they lost nearly all value. The name attached to a work affects not only its price but also the attention it gets. A change in the attribution of the Man in with the Golden Helmet, previously celebrated as a painting by Rembrandt, to one of his students, led to its removal from the permanent exhibition in the German National Gallery in Berlin.

Reputational Trajectories

Propositions about the development of recognition derive largely from life histories, usually of successful individuals, treated by their authors as slated for success. Some endowment or ability is an obvious prerequisite but not enough by itself. Reputations diffuse through of social networks and nothing really counts unless enough people take notice. Admirable deeds, repeatedly honest performance, even a remarkable achievement or transcending some overpowering obstacle if by a habitual recluse is easily ignored while comparable ones by more gregarious individuals are much more likely to be fully acknowledged. Collective approval by peers and members in the same in-group, obtained more easily than more general renown, is the usual first step up the ladder but still not so high that others have to look way up for a good view. Farther ascend to the level of the renown becomes contingent on the ability of the individual to extend these home-grown networks. Some who achieved fame had indeed everything going for them from early on – a stable family, early signs of talent nurtured by elders, a background and sufficiently well connected to the right background and connections that can help, backed by the confidence in their ability to promote themselves. All these are great reputational assets but being deficient in one or more of them asset may be an obstacle but not always an insurmountable barrier that prevents otherwise endowed individuals from developing a reputation and from ascending to even the pinnacles of fame. Great strength in one asset can even substitute for weakness in another. For Albert Einstein, probably the most renowned among the ones with an apparent handicap, it was failing a major school examination; for Glenn Cunningham, the champion miler for several years, it was a childhood accident, in which he suffered such serious burns on his legs that his doctors were not at all sure whether he would ever walk again. And, quite apart from the proverbial late bloomers, dire poverty in childhood was a serious obstacle for innumerable others.

The reputation of a person, institution, or product is the image that other individuals develop from a combination of their own observations but only to the extent that they are confirmed and corrected. The qualities people ascrib to someone are not always be the ones initially possessed by that person or not in the amount credited. They therefore have to be earned. A good example is the struggle confronting an American president notwithstanding the recognition any incumbent commands immediately upon taking office. From here on how much power his office is able to wield, according to Richard Neustadt, a scholar of the American presidency, depends on how well the incumbent measures up to the expectations political insiders have of him. Neustadt locates the source of that power, not just in the Constitution and in the mandate supposedly bestowed by an electoral victory, but in what others in the Washington political community think and expect of the incumbent. Justified or not, "it is the reality on which they act, at least until their calculations turn out wrong …." (1990, p. 51). What the president must demonstrate in the many different games he plays, often all at the same time, is his ability and his will to make use of any bargaining advantages he has. Success breeds success but a pattern of repeated failure is bound to result in a loss of faith in his reputation for effectiveness within the restricted network of political insiders, which would will impair his power to persuade.

A repeatedly outstanding exercise of power or the admiration granted for some act or performance, like a deed previously considered beyond human capability or actions worthy of sainthood, can be a first step toward renown but still leave many quite sterling individuals by the wayside. Their achievements may have come too late in life or they never aspired to wider recognition. Only rarely is renown conferred posthumously on people overlooked in their lifetime. Those intent on building a reputation tend to start early in their career and hew to the right track. One of the smoothest roads toward advancement is to address a problem on whose importance there is general agreement and to exploit it for the attention and contacts such effort is bound to bring. The results may be disappointing but the respect it commands from associates could still be a springboard from which to launch a campaign for greater renown. Attaching oneself to important people is a second strategy, equally appropriate for a career in business, politics, the sciences and the arts. All in all, people who do not stray too far off the mainstream are best positioned to outpace their contemporaries at least in the early phase of their career but not necessarily in the competition for the highest honors, which ultimately are more likely to go to the innovators, who may at first have been given a hard time by a complacent and overly conservative establishment in control of all the good places but who over the longer run the renown that eludes most of its members.

Whether recognition within any group converts into renown is highly contingent on distribution and on publicity (Becker, 1982). On this front, each field of endeavor makes its

demands. Writers and publishers need booksellers; playwrights, performers and a suitable stage; and the performers themselves need recordings and bookings on major outlets, and visual artists exhibition space for public display of their often unwieldy accomplishments. Upcoming painters stymied in their ambitions by an entrenched art establishment in control of scarce public facilities and the best private outlets have formed associations to be better able *collectively* pursue the recognition so far denied them but to which they felt their accomplishments entitled them. The evident appeal of this strategy is what led the painters denigrated as 'impressionists,' an epithet for their apparent disdain for truly 'serious' subjects, to found their own exhibition group. Many more since have chosen the same course to gain visibility.

An important facilitator of anyone's rise in a world where so many interactions are with strangers is locating a devoted patron, hopefully one with the influence and means to become an effective mediator of their reputation. Willingness to invest in this role can be motivated by a desire to be in on the latest, by the prestige that being the first to spot a rising star may bring, by a charitable impulse to eradicate poverty in some deserving cultural realm, or simply by the requirements of a journalist's or a teacher's job. Then as a reputation gains momentum, it builds on itself until it starts to decline, its time having passed and new arrivals move into the limelight. Mediators are in a position to do things that most creators, lacking in the requisite skills, do not do very well for themselves and who are therefore dependent, to this extent, on the intervention of who depend to this extent, on the assistance and intervention of wealthy collectors and influential critics. Their praise, especially when consensual, has the power to stimulate museum purchases (Moulin, 1987). It can also persuade theater circuits to reserve a permanent place for a work in their repertories and boost a reputation in other ways whereas lack of attention, even more than sharp criticism, condemns an artist or a work to a marginal existence.

Courting popularity can also backfire. Insiders in one of the more esoteric fields of the arts or of knowledge are apt to spurn rather than to embrace the renown acquired by publicity hungry colleagues. To protect their elite status, they insist on a clear separation between real quality and mass appeal. The problem for Alfred Hitchcock, a highly successful Hollywood director of many popular films, was that not all film genres were equally ordained by the elite establishment. To scale this barrier, he adopted the new and more acceptable idiom and transformed himself into a genuine *auteur* (Kapsis, 1992). It is of course possible that the public has bad judgment that it is unqualified to select what is truly deserving of special approval. But this hardly explains all differences in reputations. There is, for example, little room for ambiguity in singling out the top performers in most sports, where achievements are measurable in terms of scores, wins, speed, height, weight, or distance. As a result, no more than a highly select few winners and record holders ever achieve fame beyond the fans of their sport. The critical factor here is once again the size of the talent pool. It has grown too large for a completely dispassionate and objective sorting out in terms of performance. It has given rise to a star system and celebrity cult that, although still unmistakably oriented toward performance criteria, is less than coldy objective. The media have played their part in anointing a relatively small number of outstanding athletes, not always unequivocally the best. Once so identified, they receive a huge excess of acclaim compared to nearly equal competitors who perform in relative obscurity but on whom the appeal of the game or contest for spectators depends. The consequences of this 'winner take all' situation (Goode, 1978; Frank and Cook, 1995) are distinctly unfair, especially" when the highly acclaimed achievements, from which a few profit excessively, depend on cooperation, as it does very clearly in some team sports, where the contribution of supporting players remains largely unnoticed. The problem in other areas is actually worse. Most discoveries and inventions would have been impossible without the work predecessors and current achievements, such as in rocketry, where Wernher von Braun stands out as a heroic figure, have become ever more dependent on team effort. Yet only a small number, even among scientists, would even recognize the names of the many highly competent engineers who have make space flight possible.

The survival of all reputations is equally problematical. Over time, as memories fade, the lives of most everyone, except for a diminutive number of canonical figures, end up in the dust bins of history. There is a continuous sorting out of those deemed truly memorable. As to likely survival in the collective memory, posthumous reputations are the combined effect are sustained, on the one hand, by the deceased's lifetime accomplishments on society or on some domain and, on the other, by the extent to which, even if for altogether different reasons, an accomplishment still touches the imagination of posterity. When it does, 'greatness' can be retrospectively conferred as validation of or correction to earlier valuations but this hardly ever happens. Notwithstanding these advantages, it is more likely that individuals once recognized for their accomplishments will sink into oblivion soon after their death than for some hardly knowns to be posthumously be discovered.

The renown achieved in a person's lifetime enhances the chance for reputational survival insofar as it is likely to have encouraged more contact with others uniquely qualified to serve as mediators of fame across generations (Zilsel, 1972). Kings, popes, presidents, generals, and executives benefit from the archivists at their command but those without an official position have to link up with the appropriate networks. Colleagues and subordinates (students, employees, or loyal followers might be ready at hand but would still have to be linked to the gatekeepers in control of the portals into and out of the archives. Should the advocates represented in some network be dissatisfied by their progress, they may join in a society of 'friends' to prepare the way for some kind of a monument or a museum, in which to store the papers plus all sorts memorabilia of and about the deceased or, at the minimum, to convert a former residence, birthplace, lab, or studio into a shrine. To succeed such a venture would above all have to attract funds.

The already famous, because of their wider contacts, already have an advantage over the less known. They leave more traces with more people. This can happen all on its own, without any doing on their part, as a consequence of their lifetime fame, which lends value to anything connected with them and which provides an extra incentive to collectors and archivists to go after anything of theirs, especially pictures, diaries, and correspondence, can put people into vicarious touch with the

deceased. Because the paths of the already famous will also have crossed those of other famous contemporaries, it increases the likelihood that similar material will also have been housed in other archives. Its availability means that the scholar on the hunt for data does not have to start from scratch.

Subjects themselves do, however, have some, although limited, control over the record on which their reputational fate comes to depend. Those who take care to keep and organize records strengthen their claim on the memory of posterity. A practice that has become standard for American presidents is developing plans for a library to house his papers, despite the fact that most would be saved in any event. Some of them as well as other famous people are known to have taken the further step of purging their files of items inconsistent with the image they prefer to project. Writers, too, have burned manuscripts they believed detrimental to their reputation, and there are painters who systematically destroyed all pictures executed in a style or of a quality for which they do not want to be remembered. Theodore Roosevelt did the reverse when he dictated letters intended for posterity. Thomas Hardy actually controlled the biography his wife published under her own name following the author's death (Hamilton, 1994). The same impulse shows up in instructions to estate executors to convert the residence of the deceased into a landmark or to use remaining assets to preserve his or her reputation. Not that their wishes are always followed or followed more than half-heartedly. Most notorious is Richard Nixon's effort to retain control over his secretly recorded tapes that was obviously thwarted by other interests that prevailed.

Factors affecting the survival of reputation beyond the control of the individual are, there are circumstances of birth and death. Prospective candidates for a claim on symbolic immortality can be to born into a time or to live when or where there are none to record their deeds. It so happens that the Chinese precursor of Gutenberg, allegedly the first to set moveable type, remains unknown and that of Columbus, instead of Leif Ericson, is hailed as the European discoverer of America. As to the timing or circumstances of death, a long productive life full of honors is an obvious reputational asset. So is to be struck down in the prime of life by an assassin, a tragic illness, or unfortunate accident, which has the potential to transform the victim into an icon. No one can possibly know how John F. Kennedy would have been remembered had he served out his terms or had also been reelected. Yet the halo that surrounds him because of his tragic and untimely death overshadows the modest achievements and all too apparent failures of his administration. A still more striking example is that of Anne Frank. Would her diary, translated into many languages, have had the same impact if she had survived the Holocaust? And had she survived, would she have tolerated the publication by her father of this very private document from which he excised passages that displeased him.

Having survivors who, like Anne Frank's father, have a personal stake in preserving memory of a deceased is affected by such demographic factors as marriage, fertility, and longevity. Lang and Lang (1990) in their study of posthumous reputations of British etchers found that the revival of that art form in the late nineteenth and early twentieth century had attracted an unusually large number – for that time period – of talented women, well recognized during their lifetimes and voted into the honorary society for the highly versed practitioners of that medium. Today they are much less remembered than their male peers. Contributing to the reputational disparity between the two groups was first the extraordinary longevity of these 'lady etchers' and second the large number of them who remained single or, if they ever married, had no children. They often Outlived not only their spouses but also their colleagues, close friends, publishers, dealers, admiring collectors as well as the end of the etching cycle, often by decades, so that by the time they died there was practically no one left to mourn their death and write the obligatory obit. An additional handicap was not having a mate or a daughter to whom they could have delegated the tedious task of record keeping to serve later as a source for a future biography or for a definitive catalog raisonné of the deceased printmaker's work. For many of them there is none and never will be one.

All reputational communities have boundaries. The heroes celebrated in one may be largely unknown in another. Nowhere is this more obvious than in the different statesmen, military heroes, literary figures and so forth the different nations celebrate. National perspectives even intrude into the allocation of credit for achievements universally recognized as a breakthrough. Obviously, the pioneers of space exploration who have received the greatest attention in America differ from those celebrated in the former Soviet Union. The inventor of the incandescent lamp, as remembered by Americans, is Thomas Edison, who was in fact preceded by Joseph Swan, the English inventor who exhibited the first successful carbon-filament light bulb in England, where he had the greater impact. His factory near Newcastle rivaled Edison's in prosperity. But whereas Edison immediately patented everything, Swan was slow to do so. Nor did he have a wealthy sponsor like Henry Ford, who thought him the greatest man alive and started collecting Edison memorabilia as early as 1905. Ultimately, by transporting, piece by piece, and reassembling his New Jersey laboratory in Dearborn, Michigan, Ford erected a shrine for the inventor. For swan's reputation to grow across cultural and geographic boundaries and be an inspiration, as Edison was to become, he or some sponsor had to make his achievement appear unique and the inventor behind it a veritable genius.

Time creates its own boundaries. With only so much room in an ever more crowded field, what Collins (1998) refers to as the 'law of small numbers' comes into play. Secondary figures are pushed into the background as new interests, ideas, experiences, and those who espouse them come to the fore. Within these limits, posterity still has some leeway in how it views the past, not only in selecting but also by continuously reinterpreting the achievements of works by people with a firmly established place in the canon. It reinterpets and selects anew the work of writers and artists. As Jane Tomkins (1996) pointed out with respect to Nathaniel Hawthorne, the writings most admired by his contemporaries are not the same as those that touch us most strongly today. Similarly, according to George Boas (1940), the qualities for which Da Vinci's *Mona Lisa* has been admired have significantly changed from century to century. Long-term eminence, to put it another way, derives not solely from the stubborn persistence of beliefs about persons and their deeds. It has to be multivalent and cut across domains. The larger the number of domains touched on, the greater its resilience to gradual decay.

The development, change, preservation, and decline of reputations as well as how they function have to be understood as part of an ongoing social process. Experiments and statistical studies provide useful information, mostly about outcomes, but require supplementation with case material to illuminate the extent to which reputations and their trajectories are socially determined. Qualitative evidence, especially when derived from more than one case and subjected to systematic analysis, is not to be discounted as merely anecdotal.

Abstract

In this article, a brief description of the bootstrap method for data analysis given. The use of the bootstrap for estimating standard errors and confidence intervals is reviewed and illustrated with an application to growth curves for educational testing data.

Most scientists occasionally or frequently face problems of data analysis: what data should I collect? Having collected my data, what does it say? Having seen what it says, how far can I trust the conclusions? Statistics is the mathematical science that deals with such questions. Some statistical methods have become so familiar in the scientific literature, especially linear regression, hypothesis testing, standard errors, and confidence intervals, that they seem to date back to biblical times. In fact most of the 'classical' methods were developed between 1920 and 1950, by scientists like R. A. Fisher, Jerzy Neyman and Harold Hotelling who were senior colleagues to statisticians still active today.

The 1980s produced a rising curve of new statistical theory and methods, based on the power of electronic computation. Today's data analyst can afford to expend more computation on a single problem than the world's yearly total of statistical computation in the 1920s. How can such computational wealth be spent wisely, in a way that genuinely adds to the classical methodology without merely elaborating it? Answering this question has become a dominant theme of modern statistical theory.

The Bootstrap

The following fundamental question arises in almost every statistical data analysis: on the basis of a data set $\mathbf{z}$ we calculate a statistic $s(\mathbf{z})$ for the purpose of estimating some quantity of interest. For example, $\mathbf{z}$ could be the nine cholesterol reduction scores shown in **Table 1**, and $s(\mathbf{z})$ their mean value $\bar{z} = 28.58$, intended as an estimate of the true mean value of the cholesterol reduction scores. (The 'true mean value' is the mean we would obtain if we observed a much larger set of scores.) How accurate is $s(\mathbf{z})$?

This question has a simple answer if $s(\mathbf{z})$ is the mean $\bar{z}$ of numbers $z_1, z_2, \ldots, z_n$. Then the *standard error* of $\bar{z}$, its root mean square error, is estimated by a formula made famous in elementary statistics courses.

$$\left[\sum_{i=1}^{n}(z_i-\bar{z})^2/(n\cdot(n-1))\right]^{\frac{1}{2}} \qquad [1]$$

For the nine numbers in **Table 1**, Eqn. [1] gives 10.13. The estimate of the true cholesterol reduction mean usually would be expressed as 28.58 ± 10.13, or perhaps $28.58 \pm 10.13 \cdot s$, where s is some constant like 1.645 or 1.960 relating to areas under a bell-shaped curve. With $s = 1.645$, interval (2) has approximately 90% chance of containing the true mean value.

Table 1 Nine men's cholesterol reduction scores after taking cholostyramine; the nine scores are an ordered random sample from the scores of 164 men (data from the Stanford arm of the LRC-CPPT experiment, courtesy of Drs D. Feldman and J. Farquhar, Stanford University (see Efron and Feldman, 1991)

−21.0	3.25	10.75	13.75	32.50	39.50	41.75	56.75	80.0

The bootstrap, (Efron, 1979), was introduced primarily as a device for extending Eqn. [1] to estimators other than the mean. For example, suppose $s(\mathbf{z})$ is the '25 percent trimmed mean' $\bar{z} = \{0.25\}$, defined as the average of the middle 50% of the data: we order the observations $z_1, z_2, \ldots, z_n$, discard the lower and upper 25% of them, and take the mean of the remaining 50%. Interpolation is required for cases where $0.25 \cdot n$ is not an integer. For the cholesterol data, $\bar{z} = \{0.25\} = 27.81$.

There is no neat algebraic formula like Eqn. [1] for the standard error of a trimmed mean, or for that matter almost any estimate other than the mean. That is why the mean is so popular in statistics courses. In lieu of a formula, the bootstrap uses computational power to get a numerical estimate of the standard error. The bootstrap algorithm depends on the notion of a *bootstrap sample*, which is a sample of size n drawn *with replacement* from the original data set $\mathbf{z} = (z_1, z_2, \ldots, z_n)$. The bootstrap sample is denoted $\mathbf{z}^* = (z_1^*, z_2^*, \ldots, z_n^*)$. Each z_i^* is one of the original z values, randomly selected, perhaps $z_1^* = z_7, z_2^* = z_5, z_3^* = z_5, z_4^* = z_9, z_5^* = z_7$, etc. The name *bootstrap* refers to the use of the original data set to generate 'new' data sets $\mathbf{z}^*$.

The bootstrap estimate of standard error for $\bar{z}\{0.25\}$ is computed as follows: (a) a large number 'B' of independent bootstrap samples each of size n, is generated using a random number device; (b) the 25% trimmed mean is calculated for each bootstrap sample; (c) the empirical standard deviation of the B bootstrap trimmed means is the bootstrap estimate of standard error for $\bar{z} = \{0.25\}$. **Figure 1** shows a schematic diagram of the bootstrap algorithm, applied to a general statistic $s(\mathbf{z})$.

Figure 1 A diagram of the bootstrap algorithm for estimating the standard error of a statistic $s(\mathbf{z})$; each of the B bootstrap samples is a random sample of size n drawn with replacement from the original data set $(z_1, z_2, \ldots, z_n)$.

Trying different values of B gave these bootstrap estimates of standard error for the 25% trimmed mean applied to the cholesterol data

B:	25	50	100	200	400
Bootstrap estimate of standard error:	12.44	9.71	11.50	10.70	10.48

Ideally we would like B to go to infinity. However, it can be shown that randomness in the bootstrap standard error that comes from using a finite value of B is usually negligible for B greater than 100. 'Negligible' here means small relative to the randomness caused by variations in the original data set $\mathbf{z}$. Even values of B as small as 25 often give satisfactory results. This can be important if the statistic $s(\mathbf{z})$ is difficult to compute, since the bootstrap algorithm requires about B times as much computation as $s(\mathbf{z})$.

The bootstrap algorithm can be applied to almost any statistical estimation problem. (a) The individual data points z_i need not be single numbers; they can be vectors, matrices, or more general quantities like maps or graphs. (b) The statistic $s(\mathbf{z})$ can be anything at all, as long as we can compute $s(\mathbf{z}^*)$ for every bootstrap data set $\mathbf{z}^*$. (c) The data set '$\mathbf{z}$' does not have to be a simple from a single distribution. Other data structures, for example, regression models, time series, or stratified samples, can be accommodated by appropriate changes in the definition of a bootstrap sample. (d) Measures of statistical accuracy other than the standard error, for instance biases, mean absolute value errors, and confidence intervals, can be calculated at the final stage of the algorithm. These points are discussed in Efron and Tibshirani (1993). The more complicated example below illustrates some of them.

There is one statistic $s(\mathbf{z})$ for which we don't need the computer to calculate the bootstrap standard error, namely the mean $\bar{z}$. In this case it can be proved that as B goes to infinity, the bootstrap standard error estimate goes to $\sqrt{(n-1)/n}$ times Eqn. [1]. The factor $\sqrt{(n-1)/n}$, which equals 0.943 for $n = 9$, could be removed by redefining the last step of the bootstrap algorithm, but there is no general advantage in doing so. For the statistic $\bar{z}$, using the bootstrap algorithm is about the same as using Eqn. [1].

At a deeper level it can be shown that the logic that makes Eqn. [1] a reasonable assessment of standard error for $\bar{z}$, applies just as well to the bootstrap as an assessment of standard error for a general statistic $s(\mathbf{z})$. In both cases we are assessing the standard error of the statistic of interest by the 'true' standard error that would apply if the unknown probability distribution yielding the data exactly equalled the empirical distribution of the data. The efficacy of this simple estimation principle has been verified by a large amount of theoretical work in the statistics literature of the 1990s (see the discussion and references in Efron and Tibshirani, 1993).

Why would we consider using a trimmed mean rather than $\bar{z}$ itself? The theory of *robust* statistics, developed since 1960, shows that if the data $\mathbf{z}$ comes from a long-tailed probability distribution, then the trimmed mean can be substantially more accurate than $\bar{z}$, that is, it can have substantially smaller standard error (see, e.g., Huber, 1964). The trouble, of course, is that in practice we don't know *a priori* whether or not the true probability distribution is long-tailed. The bootstrap can help answer this question.

Figure 2 shows the bootstrap estimates of standard error for 5 different trimmed means $\bar{z}\{p\}$, 'p' being the proportion of the data trimmed off each end of the sample before the mean is taken. (So $\bar{z}\{0\}$ is $\bar{z}$, the usual mean, while $\bar{z}\{0.5\}$ is the

Figure 2 Bootstrap estimates of standard error for five different trimmed means $\bar{z}\{p\}$, $p = 0.$ 0.10, 0.25, 0.40, 0.5, applied to the cholesterol data of **Table 1**. Based on $B = 400$ bootstrap samples. Also shown is the true standard error of $\bar{z}\{p\}$, obtained by taking random samples of size nine from the population of 164 cholesterol reduction scores. In this case the bootstrap correctly indicates that $\bar{z}\{0\}$, the ordinary mean, gives the smallest standard error.

median.) These were computed using the bootstrap algorithm in Figure 1, $B = 400$, except that at step 2 five different statistics were evaluated for each bootstrap sample $\mathbf{z}^*$, namely $\bar{z}\{0\}$, $\bar{z}\{0.10\}$, $\bar{z}\{0.25\}$, $\bar{z}\{0.40\}$, and $\bar{z}\{0.50\}$.

According to the bootstrap standard errors in Figure 2, the ordinary mean has the smallest standard error among the five trimmed means. This seems to indicate that there is no advantage to trimming for this particular data set.

In fact the nine cholesterol reduction scores in Table 1 were a random sample from a much bigger data set: 164 scores, corresponding to the 164 men in the Stanford arm of a large clinical trial designed to test the efficiency of the cholesterol-reducing drug called cholestyramine (Efron and Feldman, 1991). With all of this extra data available, we can check the bootstrap standard errors. The solid line in Figure 2 indicates the true standard errors for the five trimmed means, 'true' meaning the standard error of random samples of size nine taken from the population of 164 scores.

We see that the true standard errors confirm the bootstrap conclusion that the ordinary mean is the estimator of choice in this case. The main point here is that the bootstrap estimates use only the data in Table 1, while the true standard errors require extra data that usually isn't available in a real data analysis problem.

Growth Curves

Longitudinal data are often modeled using growth curves. Our example uses educational testing data from students in North Carolina (see Williamson et al., 1991; Rogosa and Saner, 1995). The data we use for the example are eight yearly observations on achievement test scores in mathematics Y for 277 females, each followed from grade 1 to grade 8. The straight-line growth curve model for each individual can be written as

$$Y_p(t) = \xi_p(0) + \theta_p t + \varepsilon_{pt} \qquad [2]$$

where the observable scores Y contain error of measurement indicated by ε_{pt}. Here t denotes time and p denotes person. The constant rate of change for each person is indicated by θ_p; θ_p has a distribution over persons with mean μ_θ and variance σ^2_θ.

To illustrate bootstrap estimation we pick out two of the questions that are investigated using the growth curve models:

a. Can individual change be measured reliably? In behavioral and social science research the reliability index for the estimated rate of change, $\rho(\widehat{\theta})$, is the parameter of interest.
b. Is there a relation between initial standing (math achievement in grade 1) and the rate of improvement? The parameter to be estimated is correlation between θ and initial status (over the population of individuals), written as $\rho_{\theta\xi(1)}$.

Maximum-likelihood estimates of $\rho(\widehat{\theta})$ and $\rho_{\theta\xi(1)}$ can be obtained from standard mixed model analyses. Standard errors and interval estimates for these quantities are not available from widely-used computer packages.

Figure 3 shows histograms for 4000 bootstrap estimates of $\rho(\widehat{\theta})$ and $\rho_{\theta\xi(1)}$. Bootstrap samples were constructed by resampling individuals (where the data for each individual is a vector of the eight observations). The 90% confidence intervals were obtained using the so-called 'percentile method': the endpoints are the 0.05 and 0.95 percentiles of the bootstrap histograms. (The percentile method is the simplest of a number of methods for confidence interval construction via the bootstrap: a generally better method is the 'BC_a'; see Efron and Tibshirani, 1993, chap. 12–14. The results in Table 2 show good precision for estimation of the reliability, but relatively less precision for the correlation parameter.

Figure 3 Histograms of 4000 bootstrap estimates of $\rho(\theta)$ (left) and $\rho_{\theta\chi(1)}$ (right).

Related Methods

There are a number of important related methods, with strong similarities to the bootstrap. The *jackknife* systematically deletes one or more observations from the dataset, and applies the statistic to the remaining data. By doing this for each observation or groups of observations, one can obtain estimates of standard errors and bias that roughly approximate to the bootstrap estimates.

Cross-validation is similar to the jackknife but is used to assess the prediction error of a model. It systematically excludes one or more observations from the dataset, fits the model to the remaining data, and then predicts the data that was left out. Application of the bootstrap for estimating prediction error is not straightforward and requires some special modifications. With these, the bootstrap and cross-validation have similar performance for estimating prediction error. Details and references are given in Efron and Tibshirani (1993, 1997).

There is a connection of the bootstrap to Bayesian inference. Roughly speaking, the bootstrap distribution approximates a nonparametric posterior distribution, derived using a non-informative prior. Rubin (1981) gives details.

A difficult theoretical question is: when does the bootstrap work? There is much research on this question (see, e.g., Hall, 1992). In 'regular' problems where asymptotic normality can be established, first and higher order correctness of the

Table 2 Results for growth curve example

Parameter	*Estimate*	*Standard error*	*90% CI*
Reliability $\rho(\widehat{\theta})$	0.828	0.019	(0.792, 0.855)
Correlation $\rho_{\theta\xi(1)}$	0.651	0.093	(0.510, 0.814)

bootstrap (and modifications) have been proven. However, the bootstrap can fail, for example, when it is used to estimate the variance of the maximum or minimum of a sample. More generally, it is difficult to prove theoretically that the bootstrap works in complicated problems: but these are the very settings in which the bootstrap is needed most. Eventually, theory will start to catch up with practice. In the meantime, the bootstrap, like any statistical tool, should be applied with care and in the company of other statistical approaches.

Some popular statistics packages have bootstrap functions, including S-PLUS and Resampling Stats. In most packages that facilitate some customization by the user, it is easy to write one's own bootstrap function.

Conclusions

The bootstrap is a powerful tool for data analysis, with many applications in the social sciences. It is being used more and more, as fast computational tools and convenient software become widely available. Good general references on the bootstrap include Efron and Tibshirani (1993), Davison and Hinkley (1997), Hall (1992), Shao and Tu (1995), and Westfall and Young (1993).

Abstract

The steady increase in research and development (R & D) activities in modernizing societies reflects increasing specialization and professionalization in the creation of the knowledge that underlies inventions and innovations in products, processes, services, and in related systems of organization. Functionally specialized R & D departments emerged in business firms in the nineteenth century, as did complementary and more theoretical R & D activities and training in universities and related institutions. National R & D expenditures have increased with national income per head, as has the share funded and performed by business firms. However, these R & D activities are only one aspect of the invention and innovation process; a variety of other science and technology indicators have been developed and are now applied in order to reduce risks associated with bringing a product through the stages of R & D to market. Major contemporary problems in R & D relate to increasing complexity, increasing internationalization and localization, the changing role of academic research, and the barriers imposed by intellectual property protection (especially patents).

Introduction

The growth of research and development (R & D) activities reflects the increasing division of labor in the production and use of scientific and technological knowledge – a process foreseen by Adam Smith at the beginning of the Industrial Revolution. Since then, professional education, the establishment of laboratories, and improvements in techniques of measurement and experimentation have progressively increased the efficiency of discovery, invention, and innovation (Mowery and Rosenberg, 1989). While the notion of the National Innovation System largely depends on how actors, which include governments, firms, bridging institutes, and other contributing institutions, function and interact with each other to develop and apply innovative knowledge, the functioning of R & D systems for innovation has been addressed in different ways in the literature in the contexts of both advanced and latecomer countries (e.g., Hobday, 1995; Furman et al., 2002; Hu and Mathews, 2005). (Freeman (1987) is the first to propose the concept of a National Innovation System in his study of Japan's technological development, defining it as the network of institutions in the public and private sectors whose activities and interactions initiate, import, modify, and diffuse new technologies, later studies built on this with similar definitions and generally recognized this concept as comprising a complex of functions and interactions among various actors and institutions.) Despite different approaches and designs, it is widely agreed that patterns of specialization are critical for linking complex networks of innovation systems, wherein the various degrees of interaction between and among public R & D, private R & D, and university R & D are important. In particular, the influence of public R & D on specialization in high-tech industries is largely effective in East Asian latecomer countries, as they make the transition from imitation to innovation.

Building on the current literature, this article aims to discuss the influence of R & D management and its derived problems and challenges at the country, industry, and firm levels. We begin by highlighting the increased specialization in knowledge production and use, followed by the influence of R & D patterns and activities, along with problems in the processes of R & D commercialization. To relieve these problems, some of the applied methodologies and tools, as well as their economic impacts, are also elaborated on. We then conclude our findings with a discussion of the contemporary debates in R & D management, for future studies.

As addressed below, three complementary forms of specialization have developed in parallel. They are specialization by discipline, specialization by corporate function, and specialization by institution. Each contributes to the growth of R & D, as well as shaping innovative capacity at the country, industry, and firm levels.

Specialization by Discipline: The Growth of Science and Engineering

Progress and specialization in scientific disciplines accelerated in the nineteenth century with the development of more powerful research tools and techniques. Increasing opportunities for application of scientific knowledge led to the emergence of the engineering disciplines: hence chemical engineering in addition to applied chemistry, and electrical engineering in addition to applied physics (Rosenberg and Nelson, 1994). The differences in timing of the emergence of new opportunities for innovation reflected radical but uneven improvements in the knowledge base underlying technological change, and in particular the emergence of new technological paradigms (Freeman et al., 1982; Dosi, 1982).

The mechanical paradigm was the basis of the Industrial Revolution. It did not grow out of contemporaneous scientific advances, but of improvements in the quality of metals and the precision with which they could be formed and machined. These enabled the *design, development, and testing* of prototypes of families of machines with greatly improved performance based on materials of homogeneous and predictable quality,

[†] Deceased.

and on shapes with compatible sizes. Similarly, initial improvements in metal processing technologies depended less on scientific understanding than on *development* activities, experiments with different alloys and processing conditions in pilot plants. With the wide application of useful tools such as TRIZ and process simulation software, such development activities in prototype and pilot plants are typically accelerated and account for about three-fourths of the R & D expenditures of private business firms and for about two-thirds of total R & D. (TRIZ (the theory of inventive problem solving) is a problem-solving, analysis, and forecasting tool, deriving from the study of patterns of invention in the global patent literature. It was developed by the Soviet inventor and science fiction author Genrich Altshuller and his colleagues, beginning in 1946. The theory includes a practical methodology, tool sets, a knowledge base, and model-based technology for generating new ideas and solutions for problem solving. For more details, please see: http://www.triz-journal.com.)

Specialization by Corporate Function: The Growth of Business R & D

The science-based chemical paradigm (based increasingly on synthetic chemistry) and the electrical paradigm (based on electromagnetism and radio waves) laid the basis for the development of the industrial R & D laboratory, initially in the chemical and electrical firms of Germany and the USA. Many of the initial applications – including the use of techniques of chemical analysis to control the quality and composition of materials in the increasingly large-scale processing industries – were relatively mundane, but produced very profitable cost reductions. Management learned progressively that the science-based technological opportunities were applicable over a range of existing and new product markets, and therefore opened up opportunities for what is now called 'related' product diversification. Mowery and Rosenberg (1989) have described the spread of the establishment of R & D laboratories in the USA from the chemical industry to other sectors, and from larger to smaller firms. Similar processes have been at work in Europe, and more recently in East Asia (Caron et al., 1995; Nelson, 1993).

Thus, in addition to the benefits of the cognitive division of labor into more specialized fields, the functional division of labor within business firms also augmented the rate of technical change. Corporate R & D laboratories and similar groups, devoted full-time to inventive and innovative activities, provided an effective method for creating, combining, and coordinating increasingly specialized knowledge. They provided improved and specialized instrumentation, which enabled firms to monitor and benefit more systematically and effectively from advances in specialized academic disciplines. They also created techniques in the development and testing of laboratory concepts and prototypes, and translated these into commercialized products. Firms were able to experiment with a wider range of products and processes than had previously been possible when constrained by established products and production lines. In fields rich in technological opportunity, firms have consequently broadened their scopes, creating multiple products by the use of a variety of technologies.

Technological paradigms have been associated with the emergence of large dynamic firms that have been successful in exploiting new opportunities. The largest R & D spenders today are in companies that grew with the emergence of the mechanical (and automobile), biochemical, and electrical–electronic paradigms. Aerospace is a special case, having been technologically force-fed, especially since World War II, by government R & D subsidies and procurements linked with military requirements. The fastest growing R & D spenders today are those closely associated with biotechnology, ICTs (information and communication technologies), and software technology.

Specialization by Institution: The Growth of Academic Research

In the nineteenth century, de Tocqueville foresaw that the dynamics of capitalist competition would greatly stimulate the development of innovative activities that showed the prospect of a commercial return. He also argued that public authorities would need to support complementary public research of a more fundamental nature, in order to avoid diminishing returns, to open up new opportunities, and to provide trained researchers. This has happened too. In both advanced and latecomer countries, governments have become the main source of the funding of research activities, and related postgraduate training, in universities and similar institutions. Corporate R & D laboratories have come to depend increasingly on a supply of scientists and engineers aware of the latest research results and trained in the latest research techniques (Salter and Martin, 2001; Lundvall et al., 2011). In particular, based on the US Bayh–Dole Act of 1980, many East Asian latecomer countries have adopted an equivalent model since the late 1990s. This has made universities, in coordination with public research institutes, act as critical sources of knowledge production and diffusion for the industrial development of the nation (Mathews and Hu, 2007).

R & D and Modernization

This historical pattern of specialization and growth in knowledge production has been broadly repeated in the processes of modernization of latecomer countries, and is observable in countries at different levels of development today. R & D expenditures as a percentage of Gross Domestic Product (GDP) increase with GDP per head, both in specific countries over time, and in cross-sections of countries at any point in time. In successful modernizing countries, R & D is preceded by systematic business investments in improvement-generating activities: in particular, in production engineering, quality control, and design activities, initially making minor modifications and improvements, and later becoming the basis for indigenous innovative activities (Lall, 1992; Bell, 1984; Hu and Mathews, 2005). At this stage, business-funded R & D increases rapidly, accompanied by the growth of university-based research in underlying disciplines, with both reflected in the growth of international patents granted and scientific papers published. This pattern can be observed most clearly in both

South Korea and Taiwan during the 1980s and 1990s, and China since the 2000s.

The centrally planned Soviet model of modernization, practiced in the former USSR and imposed or adopted elsewhere, gave high priority to R & D. By the late 1950s and early 1960s, R & D expenditures in Central and Eastern European countries were apparently higher than those in Western Europe and the USA. Certain Western observers, therefore, concluded that the Soviet system was superior in promoting R & D and technical change. However, Soviet economic performance subsequently deteriorated, and it later became clear that a very high proportion of Soviet R & D was oriented toward weapons development, and that the government-established R & D laboratories established for each industry were decoupled from the requirements of producers and consumers (Hansen and Pavitt, 1987). The major reductions in R & D activities since their collapse in 1989 can be seen as painful adjustments to make R & D activities – and the underlying activities in production engineering, quality control, and design – become an integral part of a process of economic modernization (Dyker and Radosevic, 1999).

The Soviet system also had inadequate linkages with technical advance in the rest of the world economy. One important feature distinguishing today's modernizing countries from those of the nineteenth century is the availability of more productive technologies in more advanced countries. Countries successful in assimilating these more advanced technologies have had two characteristics (Hobday, 1995): firstly, strong linkages with the more advanced countries' technology, whether through inward direct investment (e.g., Singapore), inward technology licensing by locally owned firms (e.g., Japan, South Korea), or subcontracting agreements from advanced countries to local firms (e.g., Taiwan); secondly, the development of local, change-generating activities, culminating in R & D activities that were essential inputs to effective imitation, as well as to innovation (Cohen and Levinthal, 1989). In particular, the involvement of public R & D in the emerging technologies not only essentially catalyzed and induced the specialization of corporate R & D activity but also acted as a facilitator, associated with university R & D, to bridge the knowledge gap between advanced countries and latecomer countries in the transitional process from imitation toward innovation (Hu and Mathews, 2005).

Patterns of R & D Activity

By the beginning of the 1960s, initiatives by the US National Science Foundation and the Organization of Economic Co-operation and Development had established common definitions of R & D activities, and led to the collection by governments of systematic data on R & D activities. These have since been complemented by privately funded surveys comparing the R & D activities of individual business firms. They show the following common and largely invariant features of R & D activities.

1. In industrially advanced countries, business and government are the main sources of funding for R & D activities. Business funding is in general larger and spent in-house, mainly on *applied research and development* activities. Government funding is divided between *basic research* performed mainly in university-type institutes, and various types of R & D associated with health, the environment, defense, and the support of industry and agriculture. This R & D is performed mainly in the laboratories of government agencies and business firms.
